

1586. Binary Search Tree Iterator II

Description

Implement the `BSTIterator` class that represents an iterator over the **in-order traversal** of a binary search tree (BST):

- `BSTIterator(TreeNode root)` Initializes an object of the `BSTIterator` class. The `root` of the BST is given as part of the constructor. The pointer should be initialized to a non-existent number smaller than any element in the BST.
- `boolean hasNext()` Returns `true` if there exists a number in the traversal to the right of the pointer, otherwise returns `false`.
- `int next()` Moves the pointer to the right, then returns the number at the pointer.
- `boolean hasPrev()` Returns `true` if there exists a number in the traversal to the left of the pointer, otherwise returns `false`.
- `int prev()` Moves the pointer to the left, then returns the number at the pointer.

Notice that by initializing the pointer to a non-existent smallest number, the first call to `next()` will return the smallest element in the BST.

You may assume that `next()` and `prev()` calls will always be valid. That is, there will be at least a next/previous number in the in-order traversal when `next()` / `prev()` is called.

Example 1:

Input

```
["BSTIterator", "next", "next", "prev", "next", "hasNext", "next", "next", "next", "hasNext", "hasPrev", "prev", "prev"]
[[7, 3, 15, null, null, 9, 20], [null], [null], [null], [null], [null], [null], [null], [null], [null], [null], [null]]
```

Output

```
[null, 3, 7, 3, 7, true, 9, 15, 20, false, true, 15, 9]
```

Explanation

```
// The underlined element is where the pointer currently is.
BSTIterator bSTIterator = new BSTIterator([7, 3, 15, null, null, 9, 20]); // state is _ [3, 7, 9, 15, 20]
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 3
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 7
bSTIterator.prev(); // state becomes [3, 7, 9, 15, 20], return 3
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 7
bSTIterator.hasNext(); // return true
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 9
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 15
bSTIterator.next(); // state becomes [3, 7, 9, 15, 20], return 20
bSTIterator.hasNext(); // return false
bSTIterator.hasPrev(); // return true
bSTIterator.prev(); // state becomes [3, 7, 9, 15, 20], return 15
bSTIterator.prev(); // state becomes [3, 7, 9, 15, 20], return 9
```

Constraints:

- The number of nodes in the tree is in the range `[1, 105]`.
- `0 <= Node.val <= 106`
- At most `105` calls will be made to `hasNext`, `next`, `hasPrev`, and `prev`.

Follow up: Could you solve the problem without precalculating the values of the tree?
