2309. Greatest English Letter in Upper and Lower Case

Given a string s consisting of English letters, the task is to find the largest letter (by the position in the alphabet) that exists both

Problem Description

in lowercase and uppercase in the string s. The result should be the uppercase version of this letter. If there are no such letters that exist in both cases, return an empty string. The concept of being "larger" is determined by the standard order of letters in the English alphabet, meaning 'B' is greater than 'A', 'C' is greater than 'B', and so on up to 'Z'. Intuition

For an efficient solution, one could use bit manipulation to keep track of which letters are present in the string s in both

the least significant bit would represent 'a' or 'A', the second least significant bit 'b' or 'B', and so on. As you iterate through the string, if you encounter a lowercase letter, you calculate its positional index (by subtracting the ASCII value of 'a' from that of the letter) and then set the corresponding bit in mask1. Similarly, for an uppercase letter, you calculate the index (subtracting 'A') and set the corresponding bit in mask2.

lowercase and uppercase forms. To do so, you can create two bit masks: one for lowercase letters (mask1) and one for uppercase

letters (mask2). The idea is to use each bit in these masks to represent the presence of each letter in the alphabet— for example,

After scanning all letters in the string and updating the bit masks, you compute the bitwise AND of the two masks (mask1 & mask2). This will give you a new mask that has bits set only at positions where both a lowercase and uppercase instance of that letter exists in s.

Solution Approach The solution approach uses bit manipulation techniques to efficiently track whether each letter in the English alphabet appears as

Algorithm Steps:

both a lowercase and uppercase in the string s.

For each character c, determine if it's lowercase or uppercase.

uppercase letters, respectively. Loop through each character c in the string s.

Initialize two variables mask1 and mask2 to 0. Each will serve as a bitmask to track the occurrence of lowercase and

∘ If it is lowercase, find the difference between the ASCII values of c and 'a'. This difference gives the index (0 for 'a', 1 for 'b', ..., 25 for 'z').

masks). mask = mask1 & mask2.

 Set the corresponding bit in mask1 by shifting 1 left by the index calculated above. This is done with mask1 |= 1 << (ord(c) - ord("a")). If the character is uppercase, perform a similar operation as step 3 but on mask2 by finding the difference between the ASCII values of c and 'A'.

After completing the loop, use a bitwise AND operation between mask1 and mask2 to find common letters (bits set in both

Find the greatest (most significant) bit set in mask. This is done using mask.bit_length(), which returns the number of bits

If mask is not zero, convert the index of the greatest bit set back to an uppercase letter using chr(mask.bit_length() - 1 + ord("A")).

If mask is zero, which means no bit is set and no such common letter in both cases exists, return an empty string.

necessary to represent mask in binary, which is also the position of the highest bit set plus one.

• Two integer bit masks (variables mask1 and mask2) to track the presence of each lowercase and uppercase letter, efficiently using bitwise operations.

Bit Manipulation: To compactly store and compute the presence of letters and to find the greatest letter present in both

By following this approach, the algorithm uses constant space regardless of the size of the input string and linear time in terms of

forms. **ASCII Value Calculations:** To map characters to their respective positions in the bitmask and vice versa.

Example Walkthrough

the length of the string s.

common letters.

highest set bit plus one).

Solution Implementation

lowercase mask = 0

uppercase_mask = 0

for char in s:

else:

def greatestLetter(self, s: str) -> str:

Initialize bit masks for lowercase and uppercase letters.

set the corresponding bit in the uppercase bit mask.

uppercase_mask |= 1 << (ord(char) - ord('A'))

common_letters_mask = lowercase_mask & uppercase_mask

If there are common letters, find the greatest one.

Calculate the intersection bit mask to find common letters in upper and lowercase.

The 'bit length' method returns the position of the highest 1 bit,

greatest letter ascii = common letters_mask.bit_length() - 1 + ord('A')

corresponding to the largest letter available in both cases.

// Initialize two masks to keep track of lower and upper case letters.

Calculate the most significant bit's position and convert it back to an uppercase letter.

Iterate through each character in the string.

If the character is uppercase,

return chr(greatest_letter_ascii)

public String greatestLetter(String s) {

string greatestLetter(string s) {

if (islower(c)) {

// Iterate through each character of the string

lowercaseMask |= 1 << (c - 'a');

uppercaseMask |= 1 << (c - 'A');

// It represents letters existing in both cases

int mask = lowercaseMask & uppercaseMask;

// If there is at least one common letter

// Set the corresponding bit in the lowercase mask

// Set the corresponding bit in the uppercase mask

// Gives the position of the highest-order bit that is set to 1

// that appears in both lower and uppercase in the string 's'.

return string(1, 'A' + 31 - __builtin_clz(mask));

// If there is no common letter, return an empty string

// Initialize an array to track the occurrence of characters in the string,

// sized to fit the ASCII table for uppercase and lowercase English letters.

// Iterate backwards from ASCII code 90 (Z) to 65 (A) to find the largest lexicographical

// uppercase letter that has both uppercase and lowercase forms present in the string.

corresponding to the largest letter available in both cases.

If there are no common letters, return an empty string.

greatest letter ascii = common letters_mask.bit_length() - 1 + ord('A')

// Then we add 'A' to get the ASCII value of the greatest letter

// If the character is lowercase

// If the character is uppercase

int lowercaseMask = 0;

int uppercaseMask = 0;

for (char &c : s) {

else {

if (mask != 0) {

return "";

function greatestLetter(s: string): string {

const seenCharacters = new Array(128).fill(false);

// Iterate through each character in the provided string,

} else {

Python

class Solution:

Data Structures:

Patterns Used:

We initialize mask1 and mask2 to 0. These will track lowercase and uppercase letters, respectively. We start looping through the string s. The first character is 'a', which is lowercase.

We calculate the index for 'a' by subtracting the ASCII value of 'a' from it (which is 0) and set the corresponding bit in

We apply a bitwise AND operation on mask1 and mask2, which gives us mask = 0011001100010101, showing that we have

We subtract 1 from this value to get the actual index of the letter in the mask and add the ASCII value of 'A' to convert it

If no common uppercase and lowercase letter was present in s, mask would be 0 and we would return an empty string. But in

Let's illustrate the solution approach with a small example. Suppose we have the string s = "aAbBdDxXyYzZcC" and we want to

Continuing this process, mask1 and mask2 will have bits set based on the lowercase and uppercase letters, respectively.

After processing all characters, suppose mask1 = 0011001100010101 and mask2 = 0011001100010101.

find the largest letter that exists both in lowercase and uppercase in this string.

mask1 (so mask1 now has the least significant bit set).

We use mask.bit_length() to find the highest set bit, which in this case would return 14. This means the letter we are looking for corresponds to the bit just before the 14th position in the mask (because bit_length returns the position of the

We encounter 'A', which is uppercase. We calculate its index (also 0) and set the corresponding bit in mask2.

this example, we found 'Z' as the largest letter that exists in both cases, so the final result is 'Z'.

back to the character, giving us 'Z', which is our answer. The calculation will look like chr(14 - 1 + ord('A')).

If the character is lowercase, # set the corresponding bit in the lowercase bit mask. if char.islower(): lowercase mask |= 1 << (ord(char) - ord('a'))</pre>

If there are no common letters, return an empty string. return "" Java

else:

class Solution {

if common letters mask:

int lowerCaseMask = 0, upperCaseMask = 0; // Iterate through each character in the string. for (int i = 0; i < s.length(); ++i) {</pre> char c = s.charAt(i); // If the character is a lower case letter, update the lowerCaseMask. if (Character.isLowerCase(c)) { lowerCaseMask |= 1 << (c - 'a');// If the character is an upper case letter, update the upperCaseMask. else { upperCaseMask |= 1 << (c - 'A'); // Calculate the common mask to identify letters appearing in both cases. int commonMask = lowerCaseMask & upperCaseMask; // If there is at least one letter in commonMask, calculate and return the greatest letter. if (commonMask > 0) { // Find the largest index of the set bit which represents the greatest letter. // '31 - Integer.numberOfLeadingZeros(commonMask)' gives the last (greatest) index where the bit is set. // Adding 'A' converts it back to the ASCII character. return String.valueOf((char) (31 - Integer.numberOfLeadingZeros(commonMask) + 'A')); } else { // If commonMask is zero, it means no letter exists in both cases, return an empty string. return ""; C++ class Solution { public: // This method finds the greatest letter that appears both in lower and upper case in the input string.

// Initialize two bitmasks to track the presence of 26 lowercase and 26 uppercase letters.

// The 'mask' will only have bits set that are common in both uppercase and lowercase masks

builtin clz returns the number of leading 0-bits, hence 31 - __builtin_clz(mask)

// and record its occurrence in the seenCharacters array // by setting the corresponding ASCII index to true. for (const char of s) { seenCharacters[char.charCodeAt(0)] = true;

TypeScript

```
for (let i = 90; i >= 65; --i) {
       // Check if current letter i is present in both its uppercase and lowercase forms.
       if (seenCharacters[i] && seenCharacters[i + 32]) {
           // If a valid letter is found, return the uppercase character as the result.
           return String.fromCharCode(i);
   // If no such letter is found, return an empty string.
   return '';
class Solution:
   def greatestLetter(self, s: str) -> str:
       # Initialize bit masks for lowercase and uppercase letters.
        lowercase mask = 0
       uppercase_mask = 0
       # Iterate through each character in the string.
        for char in s:
           # If the character is lowercase,
           # set the corresponding bit in the lowercase bit mask.
            if char.islower():
                lowercase mask |= 1 << (ord(char) - ord('a'))</pre>
           # If the character is uppercase,
           # set the corresponding bit in the uppercase bit mask.
           else:
               uppercase_mask |= 1 << (ord(char) - ord('A'))

       # If there are common letters, find the greatest one.
       if common letters mask:
           # Calculate the most significant bit's position and convert it back to an uppercase letter.
           # The 'bit length' method returns the position of the highest 1 bit,
```

Time and Space Complexity

return ""

return chr(greatest_letter_ascii)

Time Complexity The time complexity of the code is dominated by the loop running through every character in the input string, s. Each iteration performs a constant amount of work: bitwise operations and comparisons. As s can be of length n, the loop runs n times. Hence, the time complexity is O(n).

Space Complexity

else:

The space complexity of the code is determined by the two integer variables mask1 and mask2. Regardless of the length of the input string, these variables occupy a constant amount of space, as they are not dependent on the input size. Thus, the space complexity is 0(1) because the space used by the algorithm does not scale with the input size.
