2360. Longest Cycle in a Graph Topological Sort Depth-First Search Graph Leetcode Link Hard

Problem Description

maximum of one outgoing edge to another node. The representation of this graph is an array edges of size n, where each element edges[i] signifies a directed edge from node i to node edges[i]. If a node i does not have an outgoing edge, then it is indicated by edges[i] == -1.The task is to determine the length of the longest cycle within the graph. A cycle is a path that begins and ends at the same node. If

You are given a directed graph that consists of n nodes. These nodes are numbered from 0 to n - 1. Each node in the graph has a

no cycle exists in the graph, the function should return -1.

Intuition

To find the longest cycle in a directed graph where each node has at most one outgoing edge, we can think of this problem as

We proceed as follows: 1. Iterate over all nodes, using each as a potential cycle starting point.

exploring paths starting from each node until we either revisit a node, indicating a cycle, or reach a node without an outgoing edge.

2. For each starting node, move to the next node using the outgoing edge and mark each visited node along the path. 3. Keep tracking visited nodes to recognize when we encounter a cycle.

- 4. When we find ourselves at a node that we have visited previously, it indicates the start of a cycle. We measure the length of the path from this node back to itself to calculate cycle length.
- 5. If we reach a node without an outgoing edge (edges [i] == -1), we conclude there's no cycle from this path.
- 6. We keep track of the maximum length found as we explore cycles from different starting points.
- The solution provided uses these steps with an array vis[] to keep track of visited nodes, ensuring each node is processed only once, which helps in maintaining a linear time complexity relative to the number of nodes.
- Solution Approach

The implementation of the solution follows the steps outlined in the intuition: 1. Initialize a list vis with n elements, all set to False, to record whether a node has been visited (True) or not (False).

3. Iterate over all nodes i (from 0 to n-1). For each node:

cycles later).

Return ans.

Example Walkthrough

a. If vis[i] is True, the node has already been visited in some previous path exploration, so we skip to the next node.

termination of the loop), inf (infinity) is used as the default value.

Suppose we are given the following directed graph as an edges array:

- b. If vis[i] is False, initialize an empty list cycle to store the path taken starting from the current node (it helps us identify
- c. Inside a while loop, visit nodes following the outgoing edges (edges [j]) until you reach a node with no outgoing edge (-1) or

2. Set a variable ans to -1. This will hold the length of the longest cycle found so far.

1 - For each visited node 'j', set 'vis[j]' to 'True' and append 'j' to the 'cycle' list. 2 - Update 'j' to be the next node to visit, i.e., 'j' becomes 'edges[i]'.

revisit a node (indicating a cycle).

i. 5. If the loop ended due to revisiting a node j:

a. Determine the index k in cycle where the node j occurs, indicating the start of the cycle. This is done using a generator

expression that searches for the first occurrence of j in cycle. If j is not found (which won't be the case here since j caused the

4. Once the while loop ends, check if it was due to reaching a node without an outgoing edge. If j == -1, continue to the next node

b. Calculate the length of the cycle as the difference between the total number of nodes in the cycle list and the index k. This gives us the length from the start of the cycle to the end of cycle.

7. After the loop over all nodes completes, the variable ans holds the length of the longest cycle, or -1 if no cycle was found.

The solution makes efficient use of the vis array for marking visited nodes to avoid reprocessing and the cycle list for tracking the

current path to identify cycles quickly. The algorithm's complexity is O(n) since each node and edge is visited at most once.

Let's walk through an example to illustrate the solution approach using the steps outlined above.

6. Update ans by taking the maximum of the current ans and the length of the cycle found in step 5b.

1 edges = [1, 2, -1, 4, 5, 3]This graph has 6 nodes (n = 6). The edges array implies:

 Node 1 has an outgoing edge to node 2. Node 2 has no outgoing edge (indicated by -1).

• Begin a while loop: Visit node 1, set vis[0] = True, append to cycle = [0]. Visit node 2, set vis[1] = True, append to cycle

1. Start with initialization:

3. For i = 0:

6. For i = 3:

2. Begin iterating over all nodes:

No cycle is detected.

Set vis[2] = True.

vis = [False, False, False, False, False] \circ ans = -1

We are going to determine the length of the longest cycle.

Node 0 has an outgoing edge to node 1.

Node 3 has an outgoing edge to node 4.

Node 4 has an outgoing edge to node 5.

Node 5 has an outgoing edge to node 3.

vis[0] is False, so we proceed. Start an empty list cycle = [].

= [0, 1]. Since node 2 has no outgoing edge, the loop ends.

- 4. For i = 1: vis[1] is already True, so we skip this iteration.
- 5. For i = 2:
- o vis[3] is False, so we proceed. Start an empty list cycle = [].
- \circ Determine the index k in cycle where node 3 occurs, k = 0. Calculate the length of the cycle: len(cycle) - k = 3 - 0 = 3.

 \circ Update ans = max(-1, 3) = 3.

num_nodes = len(edges)

visited = [False] * num_nodes

for node in range(num_nodes):

if current_node == -1:

 $longest_cycle_length = -1$

Iterate over each node

if visited[node]:

continue

from typing import List

We revisited node 3, which indicates a cycle.

7. For i = 4 and i = 5: Both vis [4] and vis [5] are True, so we skip these iterations.

After completing the loop, we find that ans = 3, which indicates that the longest cycle in the graph has a length of 3. Hence, the

cycle = [3, 4]. Visit node 3 (again), set vis[5] = True, and append to cycle = [3, 4, 5].

vis[2] is False. However, node 2 has no outgoing edge (edges[2] == −1), so we can't start a cycle from here.

Begin a while loop: Visit node 4, set vis[3] = True, append to cycle = [3]. Visit node 5, set vis[4] = True, append to

function would return 3.

def longestCycle(self, edges: List[int]) -> int:

Initialize the number of nodes in the edge list

Initialize the node for cycle checking

that points to -1 or it has been visited

The given Python code aims to find the length of the longest cycle in a directed graph where the list edges represents adjacency information: an index i points to edges[i].

Time Complexity

edges until it either hits a previously visited node (indicating the beginning of a cycle) or an end (-1). • The worst-case scenario for time complexity occurs when each node is part of a complex cycle. The outer loop runs n times

where n is the number of nodes. For each node, the inner while loop could potentially run up to n times in the case of one long

For each node, the algorithm checks whether it has been visited. If a node is unvisited, it starts a DFS-like traversal by following

cycle. Therefore, the worst-case time complexity of the algorithm is 0(n^2). **Space Complexity**

The vis list is used to keep track of visited nodes, and its size is n. • The cycle list, in the worst case, might contain all nodes if there is a single cycle involving all nodes, which would also be n. Hence, the overall space complexity is O(n) due to the storage required for the vis and cycle lists, which grow linearly with the

number of nodes n.
