# **Problem Description**

Hard

can include two special characters: A period/dot (.) which matches any single character.

This problem asks you to implement a function that determines if the given input string s matches the given pattern p. The pattern p

An asterisk (\*) which matches zero or more of the element right before it.

until the previous character, i.e., f[i - 1][j].

The goal is to check if the pattern p matches the entire string s, not just a part of it. That means we need to see if we can navigate

through the entire string s using the rules defined by the pattern. Intuition

The intuition behind the provided solution is using dynamic programming to iteratively build up a solution. We create a 2D table f

## where f[i][j] will represent whether the first i characters of s match the first j characters of p.

The approach is as follows:

1. Initialize the table with False, and set f[0][0] to True because an empty string always matches an empty pattern.

2. Iterate over each character in the string s and the pattern p, and update the table based on the following rules:

- ∘ If the current character in p is \*, we check two things: a. If the pattern without this star and its preceding element matches
- the current string s up to i, i.e., f[i][j] = f[i][j 2]. b. If the element before the star can be matched to the current character in s (either it's the same character or it's a .), and if the pattern p up to the current point matches the string s up
- o If the current character in p is . or it matches the current character in s, we just carry over the match state from the previous characters, i.e., f[i][j] = f[i - 1][j - 1]. 3. At the end, f[m] [n] contains the result, which tells us if the whole string s matches the pattern p, where m and n are the lengths of s and p, respectively.
- The key here is to realize that the problem breaks down into smaller subproblems. If we know how smaller parts of the string and pattern match, we can use those results to solve for larger parts. This is a classic dynamic programming problem where optimal
- reused) are the main components. **Solution Approach**

subproblems. The key to this solution is a 2D table f with the dimensions  $(m + 1) \times (n + 1)$ , where m is the length of the string s

and n is the length of the pattern p. This table helps in storing the results of subproblems so they can be reused when necessary.

The solution involves dynamic programming – a method for solving complex problems by breaking them down into simpler

substructure (the problem can be broken down into subproblems) and overlapping subproblems (calculations for subproblems are

## 1. Initialize the DP Table: Create a boolean DP table f where f[i][j] is True if the first i characters of s (sub-s) match the first j

matches empty p.

f[i - 1][j].

The algorithm proceeds as follows:

on the last character of the sub-pattern p[0...j]:

state of the entire string s against the entire pattern p.

of p and their meaning based on regex rules.

2. Handle Empty Patterns: Due to the nature of the \* operator, a pattern like "a\*" can match an empty sequence. We iterate over the pattern p and fill in f[0][j] (the case where s is empty). For example, if p[j-1] is \*, then we check two characters back and if f[0][j-2] is True, then f[0][j] should also be True.

3. Fill the Table: The main part of the algorithm is to iterate over each character in s and p and decide the state of f[i][j] based

characters of p (sub-p), and False otherwise. We initialize the table with False and set f[0][0] to True to represent that empty s

a. If the last character of sub-p is \*, there are two subcases: • The star can be ignored (match 0 of the preceding element). This means if the pattern matches without the last two

characters (\* and its preceding element), the current state should be True(f[i][j] = f[i][j-2]).

b. If the last character of sub-p is not \*, we check if it's a dot or a matching character:

- The star contributes to the match (match 1 or more of the preceding element). This happens if the character preceding \* is the same as the last character in sub-s or if it's a dot. If f[i - 1][j] is True, we can also set f[i][j] to True (f[i][j] |=
- o If the characters match or if the character in p is . (which matches any character), the current state depends on the previous state without these two characters: f[i][j] = f[i - 1][j - 1].

4. Return the Result: Once the table is filled, the answer to whether s matches p is stored in f[m][n], because it represents the

In essence, the solution uses a bottom-up approach to fill the DP table, starting from an empty string/pattern and building up to the

full length of s and p. The transition between the states is determined by the logic that considers the current and previous characters

Example Walkthrough

Let's take a small example to illustrate the approach described above. Consider s = "xab" and p = "x\*b.". We want to determine if

characters of p (sub-p). The table has dimensions (len(s) + 1) x (len(p) + 1), which is  $(4 \times 4)$ : 1 2

1. Initialize the DP Table: We create a table f where f[i][j] will be True if the first i characters of s (sub-s) match the first j

### F 2

F

becomes True:

F

2 | F

2

| T | F | T | F

3

F

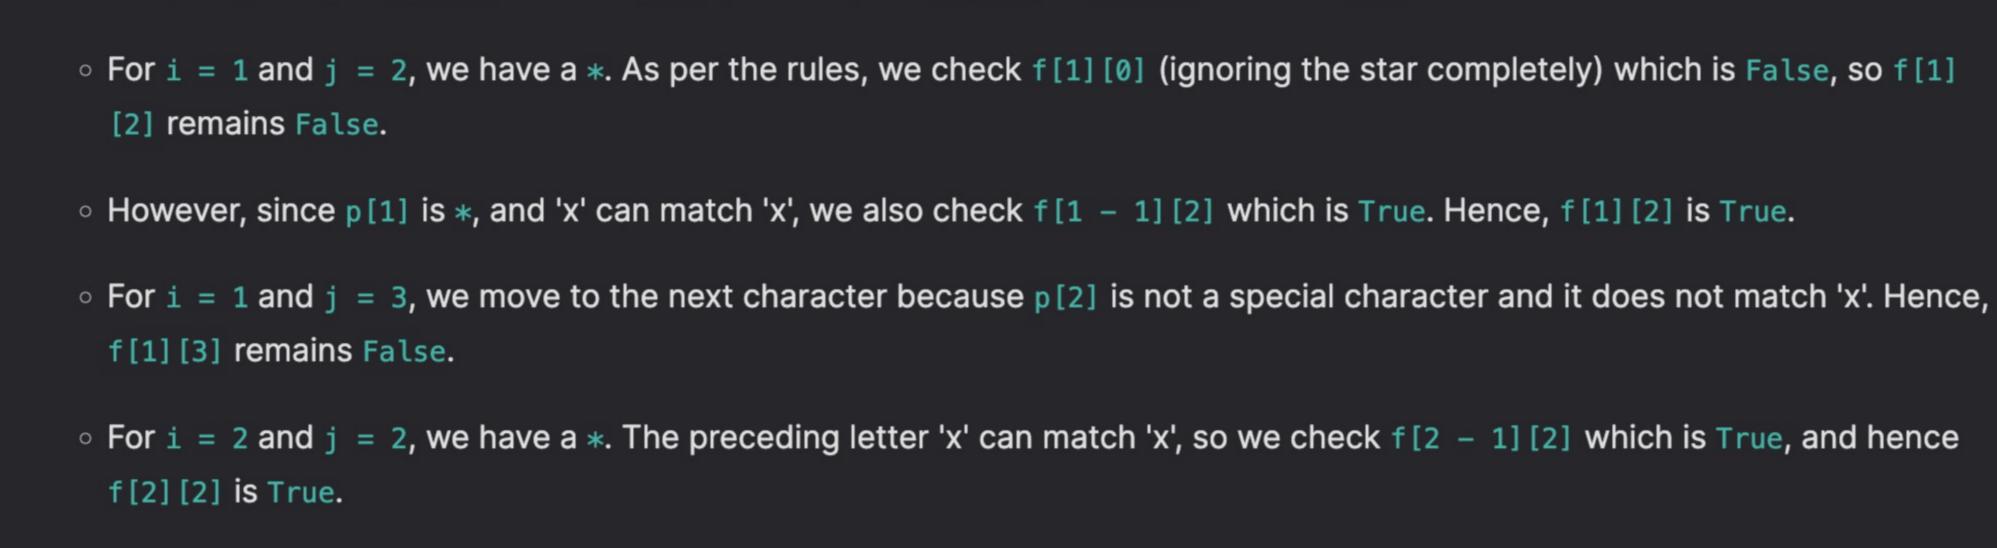

the pattern matches the string.

| T | F | F | F

2. Handle Empty Patterns: We iterate over p and update f[0][j]. Since p[1] is \*, we can ignore "x\*" for an empty s, so f[0][2]

Here, T denotes True, and F denotes False. f[0][0] is True because an empty string matches an empty pattern.

F 3 3. Fill the Table: Now, we iterate over the string s and pattern p.

∘ For i = 3 and j = 2, we have a \*. We consider matching zero or multiple 'x'. Since f[2][2] is True, and 'x' can match 'x', f[3] [2] becomes True.

def isMatch(self, text: str, pattern: str) -> bool:

# Initialize DP table with False values

# Empty pattern matches an empty text

# Iterate over text and pattern lengths

if pattern[j - 1] == "\*":

public boolean isMatch(String text, String pattern) {

boolean[][] dp = new boolean[textLength + 1][patternLength + 1];

// Function to check if string 's' matches the pattern 'p'.

// Base case: empty string matches with empty pattern

vector<vector<bool>> dp(m + 1, vector<bool>(n + 1, false));

bool isMatch(string s, string p) {

dp[0][0] = true;

return dp[m][n];

// Fill the dp table

int m = s.size(), n = p.size();

for (int i = 0;  $i \le m$ ; ++i) {

for (int j = 1;  $j \le n$ ; ++j) {

if (p[j-1] == '\*') {

dp[i][j] = dp[i][j - 2];

dp[i][j] = dp[i - 1][j - 1];

int textLength = text.length();

int patternLength = pattern.length();

for j in range(1, pattern\_length + 1):

dp[i][j] = dp[i][j - 2]

for i in range(text\_length + 1):

dp[0][0] = True

text\_length, pattern\_length = len(text), len(pattern)

dp = [[False] \* (pattern\_length + 1) for \_ in range(text\_length + 1)]

# Additional check for one or more occurrences

# Get lengths of text and pattern

 $\circ$  For i = 3 and j = 3, p[2] is '.' and it matches any character, so f[3][3] = f[2][2], hence f[3][3] is True. The final table looks as follows:

By setting up this table and following the rules, we can confidently say that "xab" matches the pattern "x\*b.".

For i = 1 and j = 1, s[0] matches p[0] ('x' == 'x'). So f[1][1] = f[0][0] which is True.

F | F | 4. **Return the Result**: The answer is stored in f[m] [n], which is f[3] [3]. It is True, so s matches p.

# If the pattern character is '\*', it could match zero or more of the previous element

// dp[i][j] will be true if the first i characters in the text match the first j characters of the pattern

∘ For i = 2 and j = 3, p[2] is '.' and it matches any character, while f[1][2] is True. Therefore, f[2][3] is True.

if i > 0 and (pattern[j - 2] == "." or text[i - 1] == pattern[j - 2]): 20 dp[i][j] |= dp[i - 1][j]# If the current characters match or if pattern has '.', mark as true 22 23 elif i > 0 and (pattern[j - 1] == "." or text[i - 1] == pattern[j - 1]):24 dp[i][j] = dp[i - 1][j - 1]

# Time and Space Complexity

// The function can be tested with an example call

This is because the solution iterates through all combinations of positions in s and p using nested loops.

In terms of space complexity, the code uses 0(m \* n) space as well due to the creation of a 2D array f that has (m + 1) \* (n + 1)elements to store the state of matching at each step.

The time complexity of the provided code is 0(m \* n), where m is the length of the input string s and n is the length of the pattern p.

// console.log(isMatch('string', 'pattern')); // Replace 'string' and 'pattern' with actual values to test.
