2274. Maximum Consecutive Floors Without Special Floors

Problem Description

Medium Array Sorting **Leetcode Link**

Alice is managing a company with office space spanning several floors of a building. She has rented floors from a certain bottom floor to a certain top floor. Not every floor is for work; some special floors are intended for relaxation. The problem provides us with the range of floors Alice has rented by specifying two integers bottom and top, indicating that all floors between and including these two are rented. We must also account for the array special, which contains the specific floors designated for relaxation.

Our objective is to determine the maximum number of consecutive floors that are not dedicated to relaxation. In other words, we want to find the longest stretch of floors that are uninterrupted by special floors where employees can work without encountering a relaxation space.

Intuition

of the total floor range. Consecutive floors without a special floor can only exist within these gaps. Here's the step-by-step intuition behind the solution:

To solve this, we can approach the problem by focusing on the gaps between the special floors, as well as the beginning and the end

1. Sort the special array. Sorting helps us to easily process the special floors in ascending order, allowing efficient comparison

- between adjacent special floors and to easily identify the maximum gap between them. 2. Find the maximum gap at the beginning. The first gap is between the bottom floor Alice rented and the first special floor. This is
- special floor itself cannot be included). 3. Find the maximum gap at the end. Similarly, the last potential gap is between the last special floor and the top floor Alice rented. This is the difference between the top variable and the last element in the sorted special array.

simply the difference between the first element in the sorted special array and the bottom variable (subtracting one since the

- 4. Find the maximum gap between the consecutive special floors. We iterate over the sorted special array and calculate the difference between each pair of adjacent special floors, subtracting one to exclude the special floor itself.
- 5. The answer is the largest of the gaps found in steps 2, 3, and 4. This maximum number represents the longest stretch of floors available without any special floor interruptions, thus fulfilling Alice's requirement.
- to find and return the maximum number of consecutive floors without a special floor.

The provided Python function maxConsecutive implements this thought process using a sorted list of special floors and comparisons

Solution Approach

encompassed between bottom and top, given the special floors.

Here's a comprehensive walk-through of the solution's implementation: 1. Sorting the Special Floors: The algorithm begins by sorting the array special. This is critical, as it ensures that the floors are

The solution utilizes a sorting algorithm and a single pass iteration to determine the longest sequence of non-special floors

method on arrays (list.sort()) is employed here, which typically provides (O(n \log n)) time complexity, where n is the number of elements in the special array.

special floor and the last rented floor (top).

2. Initializing Maximum Gaps: We initialize ans with the maximum gap possible at the beginning or end of the range. This is done by checking the first and last item of the sorted special array: To check the gap at the beginning, the algorithm computes special[0] - bottom. This gives the count of floors between the

evaluated in sequential order, which is necessary for identifying the consecutive gaps between them optimally. Python's sort

- first rented floor (bottom) and the first special floor. • To check the gap at the end, the algorithm calculates top - special[-1]. This gives the count of floors between the last
 - The larger of these two values becomes the initial ans, as it represents the longest currently known stretch without a special floor.
 - element to the end of the array, comparing each pair of adjacent special floors: • The difference between each pair of adjacent special floors special[i] - special[i - 1] is computed, and then one is

subtracted from this value (- 1). The subtraction accounts for the fact that we exclude the starting special floor of each

3. Iterating and Comparing Consecutive Special Floors: We iterate through the sorted special array starting from the second

• The calculated value represents the number of consecutive non-special floors between the current special floor and the one preceding it.

4. Updating Maximum Gaps: After each comparison of consecutive special floors, we update ans if the number of floors between

the current pair of special floors is greater than the current value of ans, effectively keeping track of and updating the maximum stretch of consecutive non-special floors. 5. Returning the Result: After iterating through all the special floors and identifying the maximum gaps both at the start, end, and

between the special floors, ans will hold the maximum number of consecutive floors without a special floor. This value is returned

The algorithm's overall complexity is dominated by the sorting step, with (O(n \log n)) time complexity for sorting and (O(n)) for the single pass through the list, resulting in a time complexity of (O(n \log n)) overall.

Let's illustrate the solution approach using a small example. Suppose Alice rents the floors 1 through 10 (bottom = 1, top = 10) and the array of special floors for relaxation is [2, 5, 9].

1. Sorting the Special Floors: First, we sort the array special, which after sorting looks like [2, 5, 9]. Sorting isn't necessary in

this case because the array is already sorted, but it's an essential step in the general case.

Here's the step-by-step application of the solution:

as the final result.

Example Walkthrough

gap.

2. Initializing Maximum Gaps: We initialize ans with the maximum gap at the beginning or the end. The maximum gap at the beginning is special [0] - bottom which is 2 - 1 = 1. The maximum gap at the end is top - special [-1] which is 10 - 9 = 1. The larger of these values is 1, so ans is set to 1.

3. Iterating and Comparing Consecutive Special Floors: We iterate through the sorted special floors and calculate the gaps: a.

gap between the second and the third special floors is 9 - 5 - 1 = 3. This is the number of floors from floor 6 to 8.

The gap between the first and the second special floors is 5 - 2 - 1 = 2. This is the number of floors from floor 3 to 4. b. The

4. Updating Maximum Gaps: We compare the found gaps with ans. The consecutive gaps we found are 2 and 3. Since 3 is greater than the current ans value of 1, we update ans to 3.

5. Returning the Result: After evaluating all gaps, we find that the largest gap is 3. Therefore, the function maxConsecutive(bottom,

top, special) would return 3, indicating the maximum number of consecutive floors without a relaxation floor is a stretch from

floor 6 to floor 8. By following this approach, we've arrived at the solution using an example scenario by using the sorted special floors [2, 5, 9] and the provided bottom and top values.

The maximum consecutive number starts with either the gap before the first # special number or after the last special number because beyond these # points we only have consecutive numbers without interruption. max_consecutive = max(special[0] - bottom, top - special[-1])

```
gap = special[i] - special[i - 1] - 1
16
               max_consecutive = max(max_consecutive, gap)
17
           # Return the overall maximum consecutive numbers found.
18
19
           return max_consecutive
```

28
Time and Space Complexity
Time Complexity
```

The time complexity of the sorting operation is $0(n \log n)$, where n is the number of elements in the special list. After sorting, the function iterates through the special list exactly once, which has a time complexity of O(n). As the sorting operation dominates, the

Typescript Solution

sortedSpecial.unshift(bottom - 1);

overall time complexity of the code is $O(n \log n)$. **Space Complexity**

The space complexity of the algorithm is 0(1) (under the assumption that the sort is done in-place). The space used by the algorithm does not grow with the size of the input, as it uses a fixed amount of extra space (just a few variables to keep track of the
