186. Reverse Words in a String II

Two Pointers Medium String

The problem provided is one of reversing the order of words within a character array s. Each word within the array is defined as a contiguous sequence of characters without spaces, and each word is separated by a single space. The key constraint is that the reversal of the word order must be done in-place, which means the solution cannot use additional memory to store a new array or other data structure.

Leetcode Link

Intuition

should remain in its original order. An efficient way to achieve this is by applying a two-step process: Reverse each individual word.

To solve this problem, the intuition is to think about the desired end state: we want the words in reverse order, but each word itself

Problem Description

Step 1 ensures that when we perform Step 2, each word will appear in the correct order since they were individually reversed in the first step.

2. Reverse the entire character array.

Implementing Step 1 involves iterating over the character array and reversing characters within each word boundary, defined by spaces. When a space is encountered, it signals the end of the current word, prompting a reversal of all characters from the start of

that word to the character immediately before the space. For the last word, since there's no trailing space, a check is needed to trigger the reversal when reaching the end of the array. After all words are individually reversed, Step 2 simply reverses the entire array from start to end. As each word is already correctly

ordered internally, this step places the words in the reverse order. The solution employs helper method reverse that takes a subsection of the array s between indices i and j, swapping the elements

at i and j, then moving i forward and j backward, repeating this process until the subsection is completely reversed. Solution Approach

The solution approach follows a systematic process:

1. Initialize Pointers: We start by initializing two pointers, i and j, along with n that holds the length of the character array s. Here,

i will serve as the start index of a word, and j will iterate through the array to find the end of a word.

2. Iterate Through s: We begin iterating over the array with j. The loop continues until j has reached the end of the array.

space to the beginning of the next word (i = j + 1).

calling the reverse function with the indices 0 and n-1.

1 ['t', 'h', 'e', ' ', 's', 'k', 'y', ' ', 'i', 's', ' ', 'b', 'l', 'u', 'e']

- 3. Reverse Individual Words: As j encounters a space, we realize that it marks the end of a word. At this point, we call the reverse helper function with the current start index i and the end index j - 1. After the reversal of the current word, we move i past the
- The reverse helper function takes two indices and reverses the subsection of s between these indices. It does this by
- the end of the array, signaling the end of the last word, and a reversal is performed for this last word segment. 5. Reverse Entire Array: Once all words are reversed, the final step is to reverse the entire character array. This is again done by

4. Edge Case for Last Word: Since there's no trailing space after the last word, the condition j == n - 1 checks if j has reached

swapping the elements at i and j, then moves i forward and j backward, repeating the process until i meets or passes j.

The data structure used is simply the input array, and the algorithm leverages the two-pointer technique to identify and reverse each word, followed by the reversal of the entire array. The reversing of elements within the array is based on the classic pattern of using

a temporary variable to swap two elements, a fundamental operation in many sorting and reversing algorithms.

This algorithm does not use any extra space and operates entirely in-place, modifying the original array to achieve the desired result.

Example Walkthrough Let's use a simple example to illustrate the solution approach. Suppose we have an array s representing the sentence: "the sky is blue" The initial state of the array s:

Now, let's walk through the process:

1. Initialize Pointers:

 \circ As j moves forward, it encounters the first space at j = 3. This means the first word "the" (from i = 0 to j - 1 = 2) needs

3. Reverse Individual Words:

2. Iterate Through s:

i is then updated to j + 1, which is 4, the start of the next word "sky".

 \circ Finally, we reverse the entire array from 0 to n-1. After this, the array 5 looks like:

1 ['b', 'l', 'u', 'e', ' ', 'i', 's', ' ', 's', 'k', 'y', ' ', 't', 'h', 'e']

s (List[str]): A list of characters representing a string with words

def reverse_partial(section: List[str], start: int, end: int) -> None:

Helper function that reverses a substring of the list in-place.

section[start], section[end] = section[end], section[start]

section (List[str]): The list of characters which substring to be reversed

separated by single spaces.

start (int): The starting index of the substring

end (int): The ending index of the substring

1 ['e', 'h', 't', ' ', 's', 'k', 'y', ' ', 'i', 's', ' ', 'b', 'l', 'u', 'e']

○ We initialize a pointer i at 0 and n as the length of the array s, which is 15.

We start iterating forward through the array with a pointer j. Initially, j is also at 0.

to be reversed. Using the reverse helper function, the array now looks like this:

 This process is repeated for the remaining words. After reversing "sky" and "is", the array looks like: 1 ['e', 'h', 't', ' ', 'y', 'k', 's', ' ', 's', 'i', ' ', 'b', 'l', 'u', 'e']

4. Continue Iterating and Reversing Words:

- When j reaches the end of the array after "blue", j = n 1, it triggers the last reversal from i = 11 to j = 14, resulting in: 1 ['e', 'h', 't', ' ', 'y', 'k', 's', ' ', 's', 'i', ' ', 'e', 'u', 'l', 'b'] 5. Reverse Entire Array:
- internally in the correct order. All this has been achieved in-place, without using any additional memory for a new array or data structure.

Now, the character array s correctly represents the sentence "blue is sky the", with the words in reverse order, and each word

This method reverses the words in the input list in-place. Parameters:

1111111

Parameters:

while start < end:

start += 1

public void reverseWords(char[] str) {

if (str[end] == ' ') {

start = end + 1;

reverse(str, 0, n - 1);

char temp = str[i];

str[i] = str[j];

str[j] = temp;

while (i < j) {

i++;

j--;

} else if (end == n - 1) {

// First, reverse each word in the array

for (int start = 0, end = 0; end < n; ++end) {</pre>

reverse(str, start, end - 1);

reverse(str, start, end);

private void reverse(char[] str, int i, int j) {

// Move to the start of the next word

// When we find a space, reverse the previous word

// If this is the end of the last word, reverse it

// Helper function to reverse a section of the character array from index i to j

// After all words are reversed, reverse the entire array to put words into the correct order

// Swap characters from the starting and ending indices until they meet in the middle

int n = str.length;

end -= 1

Time Complexity:

let temp = arr[start];

arr[start] = arr[end];

function reverseWords(s: string[]): void {

for (let end = 0; end < n; end++) {</pre>

start = end + 1;

Time and Space Complexity The given Python code is designed to reverse the words in a string in-place. Here's the analysis of its complexity:

// After reversing all the words individually, reverse the entire array to get the final result.

• The reverse function is a part of the total operation, which is called for each word and once for the entire string. It takes O(k) time for each word, where k is the length of that word, and O(n) for the entire string, where n is the total length of the input string.

To analyze the time complexity, we observe each part of the code:

- The while loop runs through each character in the string, which takes O(n) time. Combining these, each character is involved in two operations: once in the main loop, and once when its word is reversed. Including
- the final reversal of the entire string, we have:
 - For each word of length k: 0(k) For the entire string: 0(n)

Since the sum of the lengths k of all words is n, we can order these operations as O(n) + O(n) = O(2n). However, in Big O notation, we would drop the constant to simplify the expression to O(n).

- **Space Complexity:**
 - No additional space is needed except for a few variables (i, j, n), since the reversal is done in place.

 The reverse function does not use any additional space and is performed in place. Hence, the space complexity is 0(1), which indicates constant space usage.

In conclusion, the code has a time complexity of O(n) and a space complexity of O(1).
