409. Longest Palindrome

Greedy

Problem Description

String

In this problem, we're given a string s containing a mix of lowercase and uppercase letters. Our task is to determine the maximum length of a palindrome that can be created using the letters from the string. It's important to note that case matters here; 'A' and 'a' are treated as different characters, which means a string like "Aa" wouldn't count as a palindrome.

Intuition

To solve this problem, we can use the fact that a palindrome is symmetrical around its center. This symmetry means that most letters have to appear an even number of times in the string, so they can be mirrored on both sides of the palindrome. The only exception is the center of the palindrome, which can hold a single character if the length of the palindrome is odd.

1. If it has an even count, we can use all occurrences of that letter in the palindrome.

With this in mind, we can iterate over the counts of each letter in the string. For each letter:

- 2. If it has an odd count, we can use all but one occurrence of that letter to maintain symmetry.
- Additionally, we can place exactly one character with an odd count in the center of the palindrome (if we haven't already placed a

center character). To handle this gracefully, we can use a greedy approach: always add characters in pairs to the palindrome, and if there is no center yet and we encounter an odd count, we place one of those characters at the center. The implementation uses a Counter to count occurrences of each character in s. We then iterate over these counts, and for each:

• We add to the answer the largest even number that is less than or equal to the count of the character. This is achieved by v - (v

- § 1) which subtracts one if v is odd. We potentially add one more to the answer (for the center character) if there isn't already a center character. This is determined
- by ans & 1 ^ 1 which is true if ans is even, signifying that we haven't added a center character yet, and v & 1 which is true if v is odd.

The implementation starts by counting the frequency of each character in the given string s. This is done using the Counter class from Python's collections module. The Counter class creates a dictionary-like object where the keys are the characters from s, and

Solution Approach

the values are the counts of those characters. 1 cnt = Counter(s)

```
We then initialize the ans variable to 0, which will serve as our answer to hold the length of the longest palindrome we can build.
```

1 ans = 0

Next, we iterate over the values in cnt (which are the counts of each character in the string) and for each value v:

```
this, we add the largest even number smaller than or equal to v to our answer ans. This is done by using the expression v - (v &
1), which subtracts 1 from v if v is odd, effectively giving us the largest even number.
```

1. We want to add as many characters as possible to the palindrome while maintaining its symmetrical structure. To accomplish

2. We need to consider the possibility of a central character in the palindrome. We can afford to add one such character if we

1 ans += v - (v & 1)

character in the palindrome yet, and (v & 1) checks if v is odd, indicating that this character could potentially be the center. If both conditions are true, we add 1 to ans, thereby adding a central character. 1 ans += (ans & 1 ^ 1) and (v & 1) Finally, we return the ans, which gives us the length of the longest palindrome that can be created with the characters from s.

The overall algorithm is a greedy one, as it tries to use as many characters as possible while respecting the condition that only one

haven't already added one. The expression (ans & 1 ^ 1) checks if ans is still even. If it is, it means we haven't placed a center

```
character can be in the middle of a palindrome if the length is odd. By using a Counter and iterating through its values, we efficiently
```

class Solution:

consider each unique character without having to check the entire string multiple times.

def longestPalindrome(self, s: str) -> int: cnt = Counter(s) for v in cnt.values(): ans += v - (v & 1)

```
return ans
Example Walkthrough
Let's walk through the solution approach with a small example. Suppose our input string s is "AabbcC".
```

ans += (ans & 1 ^ 1) and (v & 1)

The Counter(s) would give us {'A': 1, 'a': 1, 'b': 2, 'c': 1, 'C': 1}.

2. Now we initialize our answer ans to 0.

Initialize the length of the longest palindrome to be 0

longest_palindrome_length += count - (count % 2)

// This is equivalent to count - (count % 2).

lengthOfLongestPalindrome++;

return lengthOfLongestPalindrome;

lengthOfLongestPalindrome += count - (count & 1);

// Return the length of the longest possible palindrome.

if (maxLength % 2 == 0 && count % 2 == 1) {

// Return the length of the longest palindrome that can be created.

maxLength++;

return maxLength;

// If the current palindrome length is even and the count is odd,

// we can add one more character to the center of the palindrome.

if (lengthOfLongestPalindrome % 2 == 0 && count % 2 == 1) {

length of the longest palindrome. This represents the maximum

number of characters that can be used in both halves of the palindrome.

1. We first count the frequency of each character using the Counter class.

- ∘ For 'A' with a count of 1: ans += 1 (1 & 1) which adds 0 as 'A' has an odd count, and we can't have a pair yet. Then, ans += (ans & 1 ^ 1) and (1 & 1) will add 1, because ans is even, and 'A' could potentially be at the center.
- For 'b' with a count of 2: ans += 2 (2 & 1) adds 2 as 'b' has an even count, we can use both.

longest_palindrome_length = 0

3. We start iterating over the character counts:

 For 'c' with a count of 1: Analogously to 'A', we add 0 for pairs and do not add to the center as we already have one. For 'C' with a count of 1: Same as with 'c', we add 0 for pairs and nothing to the center.

For 'a' with a count of 1: We again add 0 for pairs of 'a'. Since we already have a center character, we don't add another.

- 4. The final ans is 3, representing the longest palindrome "AbA", which we can build from the input string s.
- So, from input string "AabbcC", the maximum length palindrome we can create is 3, and the palindrome could be "AbA".

class Solution: def longestPalindrome(self, s: str) -> int: # Count the occurrences of each character in the input string char_count = Counter(s)

9 # Iterate through the counts of each character 10 for count in char_count.values(): 11 12 # Add the largest even number less than or equal to 'count' to the

20
       // If the length of the constructed palindrome is less than the length of the original string,
       // we can add one more character (center of the palindrome).
       // This character does not need to have a matching pair.
22
       return lengthOfLongestPalindrome < lengthOfString ? lengthOfLongestPalindrome + 1 : lengthOfLongestPalindrome;
23
24 }
25
Time and Space Complexity
```

Time Complexity The time complexity of the given code is primarily determined by the traversal through the characters of the string s and the values

in the cnt (counter) object.

where n is the length of the string s. 2. The second part involves iterating through the values of the cnt object. The number of unique characters in s will be at most k,

1. The first operation is creating a frequency counter (cnt) for the characters in the string with Counter(s) which takes O(n) time

- where k is the size of the character set (such as 26 for lowercase English letters, etc.), thus this iteration is O(k). Combining these steps, since k can be at most n when all characters are unique, the overall time complexity is O(n).

The space complexity of the code includes the space required for storing the frequency of each character in the string s.

Space Complexity

1. The Counter(s) creates a dictionary with at most k key-value pairs where k is the number of unique characters in s. Hence, the space required for this is O(k).

Since k is the number of unique characters and k can be at most n, the space complexity is also 0(n) if we assume that the input

string can have a large and varied set of characters. Overall, the code has a time complexity of O(n) and a space complexity of O(n).
