1191. K-Concatenation Maximum Sum

Dynamic Programming

Problem Description

Medium Array

original integer array arr a total of k times. The challenge involves not just the repetition of the array but computing the maximum possible sum of a contiguous sub-array. This includes the possibility of a sub-array having a length of 0, which would correspond to a sum of 0.

Kadane's Algorithm: This algorithm is used for finding the maximum sum of a contiguous sub-array within a single unmodified

The problem deals with finding the maximum sum of a sub-array within a modified array, which is the result of repeating the

Intuition

array. It does this by looking for all positive contiguous segments of the array (max_ending_here) and keeping track of the maximum sum contiguous segment among all positive segments (max_so_far). The algorithm increments the sum when the

spanning across copies would not increase the overall sub-array sum.

Single Pass for Kadane's Algorithm and Prefix Sums:

In the final step, we return the answer ans modulo 10^{^9} + 7.

Update the sum of the array (s) by adding the current element x.

To tackle this problem, we need to understand a few important concepts:

- running sum is positive, and resets it to zero when the running sum becomes negative. Prefix Sum and Suffix Sum: The prefix sum is the sum of elements from the start of the array up to a certain index, and the suffix sum is the sum of elements from a certain index to the end of the array. These can be useful when handling repeated arrays, as the maximum sum can span across the boundary between two repeated segments.
- Considering these concepts, the intuition for the solution approach can be broken down into steps: • The Kadane's Algorithm is used to find the maximum sum of a contiguous sub-array from the original arr. • The sum of the entire array (s) is calculated to be used in checking if we can increase the maximum sum by including sums from multiple repetitions of arr.
- We find the maximum prefix sum (mx_pre), i.e., the largest sum obtained from the start of an array up to any index. • We find the maximum suffix sum (mx_suf), i.e., the largest sum that starts at any index and goes to the end of an array. • Based on the value of k, we decide how to combine these sums to compute the final answer:
- o If k is equal to 1, the maximum sub-array sum is only within the single original array and it's the result obtained from Kadane's Algorithm. If k is greater than 1 and the total sum of the array (s) is positive, the maximum sum could potentially span across the middle arrays completely, so we consider the array sum multiplied by (k-2) and add both the maximum prefix and suffix sums.

∘ If k is greater than 1 and the total sum of the array is non-positive, we just need to consider the maximum prefix and suffix sums, as

Finally, since the answer can be very large, we return the result modulo 10^9 + 7 to ensure it stays within the integer limits for

Solution Approach

In the provided solution, the implementation walks through the array and applies the concepts mentioned in the Intuition section.

Initialization: We start by initializing variables to store the sum of the array (s), the maximum prefix sum (mx_pre), the minimum prefix sum (mi_pre), and the maximum sub-array sum (mx_sub).

array (s).

 $10^9 + 7$.

current ans.

Returning the Result:

Example Walkthrough

Initialization:

s = 0 (sum of the array)

• For the first element 3:

mi pre = 0

= mx sub = 3

∘ For the second element -1:

• For the third element 2:

- s = 2 + 2 = 4

Returning the Result:

comprehensive solution.

from typing import List

Initialize variables

total sum += num

return result % mod

max_suffix = total_sum - min_prefix

for num in arr:

if k == 1:

class Solution:

mi_pre remains 0

- mx_pre = 4

o mx_pre = 0 (maximum prefix sum)

o mi_pre = 0 (minimum prefix sum)

o mx_sub = 0 (maximum sub-array sum)

Here's a breakdown of the logic used:

We loop through each element in arr:

the problem.

■ Update the maximum prefix sum (mx_pre) to the maximum of mx_pre and the current sum s. Update the minimum prefix sum (mi_pre) to the minimum of mi_pre and the current sum s. ■ Update the maximum sub-array sum (mx_sub) to the maximum of the current mx_sub and the difference between the current sum s

Handling Multiple Concatenations: • After the loop, we calculate the suffix maximum sum (mx_suf) by subtracting the minimum prefix sum (mi_pre) from the total sum of the

∘ If k equals 1, which means the array is not concatenated, we use the answer gotten from the Kadane's pass earlier and return it modulo

• Next, if the sum of the array (s) is positive, we explore the possibility that the maximum sum spans across the entire middle part of the

concatenated array. This leads us to consider $(k - 2) * s + mx_pre + mx_suf$. We then again update ans if this is greater than the

and the minimum prefix sum (mi_pre), which represents Kadane's algorithm execution for the sub-array ending at the current element.

• For the case where k is greater than 1, we explore the options by combining different parts of the array: • First, we use the maximum prefix sum plus the maximum suffix sum (mx_pre + mx_suf) and update ans if this is greater than the current ans.

• The base answer variable ans is initialized with the value obtained from Kadane's Algorithm (mx_sub).

- This approach effectively handles the possibility of maximizing the sub-array sum by including the sum of the entire array when it is beneficial (i.e., when the total sum is positive) due to the concatenation specified by k. It ensures that the maximum sub-array sum is found even if it spans across multiple copies of the array.
- Let's walk through an example to illustrate the solution approach: Suppose our given array is arr = [3, -1, 2] and k = 2. That means we need to find the maximum sub-array sum in an array that would look like [3, -1, 2, 3, -1, 2] after concatenating arr to itself once (as k = 2).

- s = 3mx_pre = 3

- s = 3 - 1 = 2

Single Pass for Kadane's Algorithm and Prefix Sums:

mx_pre remains 3 mi_pre remains 0 mx_sub remains 3

■ Since the sum of the array s is positive, we explore the maximum sum crossing the entire middle part which would be (k - 2) * s +

This example demonstrates that even when our given array has negative numbers, by strategically utilizing the concatenation of

the array k times, we can maximize the sub-array sum without including the negative sub-arrays. The technique of combining

prefix and suffix sums with Kadane's algorithm and handling different cases based on the total sum s and the count k leads to a

 $= mx_sub = 4 (since 4 - 0 > 3)$ Handling Multiple Concatenations:

```
∘ The function would return ans modulo 10^9 + 7, which is 8 in this case, as the maximum sum sub-array is [3, -1, 2, 3, -1, 2] itself
 when k = 2, with the sum being 8.
```

After the loop, we calculate mx_suf which is s − mi_pre = 4 − 0 = 4.

■ We calculate mx_pre + mx_suf = 4 + 4 = 8 and compare it with ans, thus ans becomes 8.

 $mx_pre + mx_suf$. Since k = 2, multiplying by k - 2 equals 0, so this step does not change ans.

 \circ Since k > 1, we examine the maximum sum using concatenation:

• The base answer ans is mx_sub which is currently 4.

Solution Implementation **Python**

def kConcatenationMaxSum(self, arr: List[int], k: int) -> int:

max prefix = max(max prefix. total sum)

total_sum = max_prefix = min_prefix = max_subarray_sum = 0

Calculate max subarray sum for a single array iteration

Update result for potential double array combination

result = max(result, max_prefix + max_suffix)

public int kConcatenationMaxSum(int[] arr, int k) {

// and minimum prefix sums.

return (int) (answer % mod);

for (int value : arr) {

sum += value;

if (k == 1) {

if (sum > 0) {

return (int) (answer % mod);

long sum = 0; // Total sum of the array elements.

maxPrefixSum = Math.max(maxPrefixSum, sum);

minPrefixSum = Math.min(minPrefixSum, sum);

long maxPrefixSum = 0; // Maximum prefix sum found so far.

long minPrefixSum = 0; // Minimum prefix sum found so far.

long maxSubarraySum = 0; // Maximum subarray sum found so far.

// Iterate over the array to find the maximum subarray sum, maximum prefix,

long answer = maxSubarraySum; // This holds the result, which is initialized to maxSubarraySum.

final int mod = (int) 1e9 + 7; // Module to perform the answer under modulo operation.

// If there's only one concatenation, simply return the max subarray sum modulo mod.

long maxSuffixSum = sum - minPrefixSum; // Maximum suffix sum after one traversal.

answer = Math.max(answer, (k - 2) * sum + maxPrefixSum + maxSuffixSum);

// If the sum of the array is positive, the best option might be to take the sum k-2 times,

maxSubarraySum = Math.max(maxSubarraySum, sum - minPrefixSum);

// Check if adding the entire array sum (suffix and prefix) is better.

answer = Math.max(answer, maxPrefixSum + maxSuffixSum);

// then add the maxPrefix and maxSuffix sums.

// Return the maximal sum found under modulo mod.

If k is 1, return the result of a single array's max subarray sum

Calculate the maximum suffix sum for potential use in concatenated arrays

result = $max(result, ((k - 2) * total_sum) + max_prefix + max_suffix)$

return result % mod # Return the result modulo the provided modulus

If the array sum is positive, calculate the max sum when array is concatenated k times

min prefix = min(min prefix, total sum) max_subarray_sum = max(max_subarray_sum, total_sum - min_prefix) # The result after a single iteration result = max subarray_sum mod = 10**9 + 7

class Solution { // Computes the maximum sum of a subsequence in an array that can be achieved by // concatenating the array k times.

Java

if total sum > 0:

```
C++
class Solution {
public:
    int kConcatenationMaxSum(vector<int>& arr, int k) {
        long sumOfArray = 0. maxPrefixSum = 0. minPrefixSum = 0. maxSubarraySum = 0;
        const int MOD = 1e9 + 7; // Define the modulus for the answer
        // Calculate the maximum subarray sum for one array
        for (int num : arr) {
            sumOfArray += num: // Sum of elements so far

result = Math.max(result, (maxPrefixSum + ((k - 2) * sumOfArray + maxSuffixSum) % MOD) % MOD);

// Handle the case when the array is concatenated only once

def kConcatenationMaxSum(self, arr: List[int], k: int) -> int:

total_sum = max_prefix = min_prefix = max_subarray_sum = 0

Calculate max subarray sum for a single array iteration

If k is 1, return the result of a single array's max subarray sum

 $(k - 2) * s + mx_pre + mx_suf if s > 0$. These operations take 0(1) time.

Hence, the overall time complexity of the function is 0(n + 1), which simplifies to 0(n).

maxSubarraySum = Math.max(maxSubarraySum, (sumOfArray - minPrefixSum + MOD) % MOD); // Kadane's algorithm update

result = Math.max(result, (maxPrefixSum + maxSuffixSum) % MOD); // Max of result and the sum of max prefix and max suffix

// If the sum of the array is positive, we include the whole arrays (k-2) times along with maxPrefix and maxSuffix

```
for num in arr:
    total sum += num
   max prefix = max(max prefix, total sum)
   min prefix = min(min prefix, total sum)
   max_subarray_sum = max(max_subarray_sum, total_sum - min_prefix)
```

class Solution:

if (k === 1) {

return result;

from typing import List

return result;

if (sumOfArray > 0) {

// Return the result modulo 10^9 + 7

Initialize variables

result = max subarray_sum

return result % mod

mod = 10**9 + 7

if k == 1:

The result after a single iteration

```
# Calculate the maximum suffix sum for potential use in concatenated arrays
       max_suffix = total_sum - min_prefix
       # Update result for potential double array combination
       result = max(result, max_prefix + max_suffix)
       # If the array sum is positive, calculate the max sum when array is concatenated k times
       if total sum > 0:
           result = max(result, ((k - 2) * total_sum) + max_prefix + max_suffix)
       return result % mod # Return the result modulo the provided modulus
Time and Space Complexity
  The given Python code defines a method kConcatenationMaxSum which finds the maximum sum of a subarray in the K-
  concatenated array formed by repeating the given array k times.
Time Complexity
  The function iterates once through the array arr, performing a constant amount of work in each iteration, including finding
  maximum and minimum prefixes, and computing the maximum subarray sum ending at any element. Therefore, the time
  complexity of iterating the array is O(n) where n is the length of arr.
  After this iteration, there is a constant amount of work done to compute mx_suf and the maximum of ans, mx_pre + mx_suf, and
```

Space Complexity

As such, the space complexity is 0(1).

number does not scale with the input size. The inputs arr and k are used without any additional space being allocated that depends on their size (no extra arrays or data structures are created). Thus, the space used is constant.

In terms of space, the function allocates a few variables (s, mx_pre, mi_pre, mx_sub, and mod), which use 0(1) space as their

Combining the analysis above, the code has a linear time complexity and constant space complexity.
