#### 1986. Minimum Number of Work Sessions to Finish the Tasks Backtracking Medium **Bit Manipulation Bitmask**

**Leetcode Link** 

**Dynamic Programming** 

# **Problem Description**

to complete. You also have a maximum duration you can work in a single work session, called sessionTime. A work session is defined as a period during which you can work for up to sessionTime consecutive hours before taking a break. The goal is to figure out the minimum number of work sessions required to complete all tasks under the following rules: 1. You must complete a task within the same work session if you start it.

You are given n tasks to complete, with their durations specified in an array called tasks, where the i-th task takes tasks[i] hours

3. The tasks can be completed in any order.

subset as a valid combination that can be completed within a single work session.

Array

2. After finishing a task, you can start a new one immediately.

Your aim is to determine the minimum number of work sessions needed to finish all the assigned tasks without violating the conditions mentioned.

accumulating the results with dynamic programming.

number of sessions required to complete the tasks in subset i.

checking if the sum is within sessionTime.

Intuition

Solving this problem involves understanding that it is a combinatorial optimization problem which suggests finding an optimal

#### combination of tasks that fit within the session time limit. Since sessionTime is guaranteed to be greater than or equal to the maximum time for a single task, no task is unstartable.

The first step towards the solution is to generate all the possible combinations of tasks that can fit within a single session. This is achieved by iterating over each possible subset of tasks, where each subset is represented by a bitmask. A bitmask is a binary representation where each bit corresponds to whether a task is included in the subset or not (1 for included, 0 for not included).

Next, we need to determine the minimum number of sessions required to complete all tasks. We initialize an array, f, to store the minimum sessions required for each subset of tasks. The value of f[i] represents the minimum number of sessions required to complete the subset i.

For each subset, we check if the total time of the tasks in that subset does not exceed the sessionTime. If it doesn't, we mark this

We use Dynamic Programming to build up the solution. For each subset i, we consider all possible valid combinations that have already been identified. We try to improve the minimum session count by checking if excluding a valid subset j from i (calculated as i XOR j) decreases the overall session count. In other words, we are trying to find the best previous state (f[i XOR j]) and then

adding one more session for the current subset j. Finally, f[-1] gives us the minimum number of sessions required to complete all the tasks, as it represents the state where all tasks have been included in some work session.

This approach efficiently finds the optimal number of work sessions by exploring and evaluating all possible task combinations and

Solution Approach The implementation of this solution relies on several key concepts, including bit manipulation and dynamic programming.

Bit Manipulation

This algorithm uses bit manipulation to represent subsets of tasks. The key insight of using bitmasks is that a subset of n tasks can

included, and the second task is excluded. This allows us to iterate over all possible subsets efficiently, using bitwise operations.

be represented as an n-bit integer. For example, if n is 3, then the binary 101 represents the subset where the first and third tasks are

# the subsets of tasks, where each index corresponds to a bitmask representing the subset. The value f[i] stores the minimum

**Dynamic Programming** 

Dynamic programming (DP) is used to build up the solution by reusing previously computed results. The DP array, f, is indexed by

## Implementation Steps

minimum. The starting state, f[0], is set to 0, because no sessions are needed when no tasks are included. 3. To compute the minimum sessions for each subset, we iterate over all subsets i. For each subset, we iterate through its submasks j. This part uses a nested looping structure where the inner loop uses a clever bit trick to iterate through all submasks

4. For each submask j, if j is a valid subset (ok[j] is True), we check if we can get a better solution by combining the sessions

required for the subset i XOR j (which means the subset i without the tasks in j) and the current submask j. If this is the case,

1. First, we initialize an array, ok, to keep track of which subsets can be completed within a single session. We populate this array

by iterating through all possible subsets (from 1 to 2<sup>n</sup> - 1), summing up the times of tasks included in each subset, and

2. Once we have identified all valid subsets, we initialize the DP array, f, with infinity (inf) to represent an initially unknown

of i. The expression (j - 1) & i ensures that we only consider submasks that are actual subsets of i.

we update f[i] with the minimum value between the current f[i] and f[i XOR j] + 1.

capabilities of dynamic programming, resulting in an optimal solution to the task scheduling problem.

Subset {1} (binary 001, total duration 1) fits in a session.

Subset {2} (binary 010, total duration 2) fits in a session.

 $\circ$  For subset  $\{1\}$  (001), f[1] = 1, as it only needs one session.

 $\circ$  For subset  $\{2\}$  (010), f[2] = 1, as it only needs one session.

 $\circ$  For subset  $\{3\}$  (100), f[4] = 1, as it only needs one session.

4. Using DP to find the minimum number of sessions:

Calculate f [5] for subset {1, 3}:

Calculate f [6] for subset {2, 3}:

from math import inf

from typing import List

 $\circ$  For subset  $\{1, 2\}$  (011), f[3] = 1, as both can be done in one session.

■ The submasks are {2} and {3}, each needing one session.

• For subsets beyond {1, 2} (011), we need to consider splitting into submasks.

5. We continue this process until we've computed the optimal session counts for all subsets. The final answer will be stored in f[-1], which represents the minimum number of work sessions needed for the complete set of tasks.

This implementation efficiently combines the powers of combinatorial enumeration via bit manipulation and the optimization

Let's assume we have n = 3 tasks with durations specified in an array called tasks = [1, 2, 3], and we have a maximum session duration sessionTime = 3.

 Subset {3} (binary 100, total duration 3) fits in a session. Subset {1, 2} (binary 011, total duration 3) fits in a session. Subsets {1, 3} (binary 101) and {2, 3} (binary 110), and {1, 2, 3} (binary 111) do not fit as their durations exceed

Initialize DP array f with infinity, except for f[0] = 0. Here, f[0] corresponds to no tasks being complete.

The f array before starting the DP process: f = [0, inf, inf, inf, inf, inf, inf, inf].

We start by generating all possible subsets of tasks and checking which can fit into a single session.

#### 3. Building up the DP table:

**Example Walkthrough** 

1. Identify valid subsets:

sessionTime.

2. Dynamic Programming Initialization:

■ The submasks are {1} (needs 1 session) and {3} (needs 1 session). ■ Since {1, 3} doesn't fit in one session, we add the session counts of the submasks: f[5] = f[1] + f[4] = 1 + 1 = 2.

5. Conclusion: The final DP array f stands as [0, 1, 1, 1, 1, 2, 2, 2]. The answer is f[7] which is 2. Therefore, the minimum

■ Since {2, 3} doesn't fit in one session, f[6] = f[2] + f[4] = 1 + 1 = 2. Finally, for the full set {1, 2, 3} (111),

■ The optimal way is to combine {1, 2} and {3}, so f[7] = f[3] + f[4] = 1 + 1 = 2.

**Python Solution**

34
Time and Space Complexity
The given Python code defines a method minSessions to find out the minimum number of work sessions required to finish all given
tasks within a specified session time. The code utilizes bitmask Dynamic Programming (DP), where each state in DP represents a
subset of tasks.
```

// 'canCompleteSession' is an array indicating for each subset of tasks whether it can be completed in a single session.

**Time Complexity:** 

Calculating the ok array requires iterating through all subsets of tasks, which are 2<sup>n</sup>, and summing up the tasks in each subset.

This yields a time complexity of  $O(n * 2^n)$  for setting up the ok array, where n is the number of tasks.

## • The nested loops for the DP solution iterate through all 2^n subsets of tasks and for each subset, go through its submasks to update the f[i]. This results in another $O(n * 2^n)$ operations (since the average number of submasks each mask has is

space complexity.

proportional to n, considering the worst case). Combine both parts, and the total time complexity is  $0(n * 2^n)$ . **Space Complexity:** 

The space is occupied by the ok array and the f array, both of which have 2<sup>n</sup> elements, resulting in 0(2<sup>n</sup>) space complexity.

Additional space usage is minimal (constant space for the iteration variables and the sum), hence not impacting the overall

- So, to encapsulate: Time Complexity: 0(n \* 2^n)
  - Space Complexity: 0(2<sup>n</sup>)
