Problem Description

The task is to create a square matrix (2-dimensional array) of a given size n where n is a positive integer. The matrix should be filled with numbers from 1 to n^2 (1 to n squared) following a spiral pattern. A spiral pattern means we start from the top-left corner (0,0) and fill the matrix to the right, then downwards, then to the left, and finally upwards, before moving inwards in a spiral manner and repeating the directions until the entire matrix is filled.

Intuition

down, left, and up. We use a variable to track the value to be filled in the next cell, which begins at 1 and ends at n^2. To navigate the matrix: 1. We maintain a direction vector dirs which contains tuples representing the direction of movement: right (0, 1), down (1, 0),

The intuition behind the solution is to replicate the spiral movement by using direction vectors to move the filling process right,

- left (0, -1), and up (-1, 0). 2. We initialize our position at the start of the matrix (0,0) 3. We iterate through the values from 1 to n^2, filling the cells of the matrix.
- 4. After inserting a value, we check if the next step will go out of bounds or into a cell that already has a value. If so, we change direction by rotating to the next direction vector.
- 5. This process is continued until all cells are filled accordingly maintaining the spiral order.

The solution uses modulo division to cycle through the directions, ensuring when we reach the end of the direction vector, it loops

back to the beginning. This helps us maintain the spiral path without creating complex conditional statements.

Solution Approach

The solution applies a simulation approach, where we simulate the spiral movement within the matrix. Let's dissect the solution

## approach.

1. We start by creating an n x n matrix filled with 0s to hold the values. This is achieved by the list comprehension [[0] \* n for \_ in range(n)].

- 2. We define a dirs array which contains four tuples. Each tuple represents the direction change for each step in our spiral: right is (0, 1), down is (1, 0), left is (0, −1), and up is (−1, 0).
- 3. We initialize three variables 1, 1, and k which represent the current row, current column, and current direction index, respectively.
- 4. A for loop is used to iterate through the range from 1 to n^2, inclusive. During each iteration, we perform the following steps:
- Calculate the next position (x, y) by adding the current direction vector dirs[k] to the current position (i, j). Check if the next position is out of bounds or if the cell has already been visited (non-zero value). If either is true, we change
  - the direction by updating the value of k with (k + 1) % 4, which rotates to the next direction vector in dirs.

Place the current value v in the ans matrix at position (i, j).

• Update the current position (i, j) to the new position (x, y) based on the direction we are moving.

By following this approach, we can generate the matrix with numbers from 1 to n^2 in spiral order dynamically for any size of n.

- 5. The loop stops when all values from 1 to n^2 have been placed into the ans matrix.
- The use of a direction vector is a common technique in grid traversal problems. It simplifies the process of moving in the four cardinal

directions without writing multiple if-else conditions. The modulo operator % assists in cycling through our direction vectors to maintain the correct spiral movement.

Example Walkthrough Let's assume n = 3 to illustrate the solution approach. Our goal is to fill a 3×3 matrix with numbers from 1 to  $3^2$  (which is 9), in a spiral pattern.

# 1. We create an empty 3×3 matrix filled with 0's.

movement respectively.

(starting with right movement).

2 [0, 0, 0], 3 [0, 0, 0], 4 [0, 0, 0]

3. We set i, j, and k to 0. Here, (i, j) is the current position (initially at the top-left corner), and k is the index for direction vectors

2. The dirs array contains direction vectors: [(0, 1), (1, 0), (0, -1), (-1, 0)]. This represents right, down, left, and up

4. We will fill the matrix with values from 1 to 9. For each value v, we do the following:

Place v at ans [i] [j]. For the first iteration, we place 1 at ans [0] [0].

o If (x, y) is out of bounds or ans [x] [y] is not 0, we update k to (k + 1) % 4 to change direction. Move to (x, y) and repeat the process.

up for 6, again move right for 7, then go to the center and fill 8, and finally move right to fill 9.

def generateMatrix(self, n: int) -> List[List[int]]:

# Iterate over all values from 1 to n^2 to fill the matrix

# Change direction if the next position is invalid

# Recalculate the next position after changing the direction

direction\_index = (direction\_index + 1) % 4

# Assign the current value to the matrix

// Place the value into the matrix.

int nextRow = row + directions[dirIndex][0];

int nextCol = col + directions[dirIndex][1];

nextRow = row + directions[dirIndex][0];

nextCol = col + directions[dirIndex][1];

dirIndex = (dirIndex + 1) % 4;

return matrix; // Return the filled matrix.

// Initialising the matrix with 'undefined' values

let matrix = Array.from({ length: n }, () => new Array(n).fill(undefined));

// Directions represent right, down, left, up movements respectively.

function generateMatrix(n: number): number[][] {

// Calculate the next position using the current direction.

// Check boundary conditions and whether the cell is already filled.

// Change direction: right -> down -> left -> up -> right ...

// Calculate the position again after changing direction.

matrix[row][col] = value;

# Initialize the matrix with zeros

for value in range(1, n \* n + 1):

1 ans = [ 2 [1, 2, 3], 3 [8, 9, 4],

5. We continue this process until all values are filled into the matrix. After the completion, the ans matrix looks like:

 $\circ$  Update the next position (x, y) by adding the direction vector to the current position (i, j).

[7, 6, 5]The steps are as follows: Start with the top-left corner (0,0), move right and fill 1, 2, 3, then move down to fill 4, move left for 5, move

Python Solution

This makes the ans matrix to have its elements in a spiral order, from 1 to 9. By doing so for any n, we can generate the desired spiral

 $matrix = [[0] * n for _ in range(n)]$ # Define directions for movement: right, down, left, and up directions = ((0, 1), (1, 0), (0, -1), (-1, 0))# Initialize the starting point and direction index row = column = direction\_index = 0

if next\_row < 0 or next\_column < 0 or next\_row >= n or next\_column >= n or matrix[next\_row][next\_column];

```
13
               matrix[row][column] = value
               # Calculate the next position
14
15
               next_row, next_column = row + directions[direction_index][0], column + directions[direction_index][1]
               # Check if the next position is out of bounds or already filled
16
```

Time and Space Complexity
The given Python code generates a spiral matrix of size n x n, where n is the input to the method generateMatrix. Let's analyze both
the time complexity and space complexity of the code.
```

**Time Complexity:** 

n operations, one for each element. Thus, the time complexity is  $0(n^2)$ .

**Space Complexity:** The space complexity includes the space taken up by the output matrix, and any additional space used by the algorithm for processing. In this case, the output matrix itself is of size  $n \times n$ , so that takes  $O(n^2)$  space. The algorithm uses a small, constant

corresponds to every position in the matrix being visited once. Since the matrix has n x n positions, the algorithm has to perform n \*

The time complexity of this algorithm is determined by the number of elements that need to be filled into the matrix, which

This means the additional space used by the algorithm does not grow with n, which makes it 0(1). However, since the output matrix size is proportional to the square of n, we consider it in the overall space complexity.

Thus, the overall space complexity of the algorithm is  $0(n^2)$ .

amount of extra space for variables and the direction tuple dirs.
