174. Dungeon Game **Dynamic Programming** Hard

Matrix

Problem Description

The problem presents a scenario where a knight must rescue a princess trapped in the bottom-right corner of a dungeon represented by a 2D grid. The grid has dimensions m x n, with each cell of the grid representing a room that may contain demons, magic orbs, or be empty. The knight begins at the top-left room and can only move rightward or downward.

The knight has an initial health value, which must always remain above 0 for him to survive. If the knight passes through a room with demons, his health decreases by the number depicted in that room; if the room contains magic orbs, his health increases

accordingly. The objective is to calculate the minimum health the knight needs to start with to ensure he can reach the princess without dying. Intuition

The key to solving this problem lies in <u>dynamic programming</u>, particularly in understanding that the optimal decision at each room

the princess's room to the knight's starting point. This way, we can always make sure the knight has just enough health to reach the next step. We initialize a 2D array (dp) that will store the minimum health required to reach the princess from any given cell. The knight's goal is to reach the cell containing the princess with at least 1 health point.

depends on the decisions made in subsequent rooms. Rather than navigating from the start to the end, we work backwards from

Starting from the princess's cell, we backtrack and calculate the minimum health needed for each previous room. The minimum

health required to enter any room is the maximum of 1 (the knight can't have less than 1 health) and the difference between the health required to enter the subsequent room and the value of the current room (which may be positive, negative, or zero). This computation proceeds until we reach the starting cell, at which point dp[0][0] gives us the minimum health that the knight

Solution Approach

We approach the solution by implementing <u>dynamic programming</u> to solve the problem in a bottom-up manner. Let's go through

the implementation using the supplied Python code.

must have to rescue the princess successfully.

checking for edge cases in each iteration.

health the knight needs to start with in order to rescue the princess.

Here's the step-by-step breakdown of the dynamic programming approach:

Let's say the dungeon grid is represented by the following 2D grid, where m = 2 and n = 3:

Initialization of the DP table: We create a 2D array dp of size (m+1)x(n+1) filled with inf (infinity). This represents the minimum health needed to reach the princess from any given cell. We fill it with inf to represent that we haven't calculated the health for any room yet. We use m+1 and m+1 for ease of implementation so that we can handle the boundary without

- **Boundary Conditions**: Set dp[m][n-1] and dp[m-1][n] to 1 because the knight needs a minimum of 1 health point to survive. These are the cells adjacent to the princess's cell. As the knight can only move rightward or downward, these cells represent the only two ways to reach the bottom-right corner without being in it. Main Loop: We iterate over the dungeon grid starting from the cell (m - 1, n - 1) which is right above and to the left of the
- princess's cell, moving backward to the start at (0, 0). For each cell (i, j), we calculate the minimum health the knight needs to proceed to either of the next cells (i + 1, j) (downwards) or (i, j + 1) (rightward). Here's the core logic: we use max(1, min(dp[i + 1][j], dp[i][j + 1]) - dungeon[i][j]), which means:
- We first determine the less risky path by finding the minimum of the health needed to move to the next cells (min(dp[i + 1][j], dp[i][j + 1])).

• We then subtract the current room's value from this health. If the current room has a demon (negative value), this effectively increases the

- health needed to handle the demon. If the room has an orb (positive value), this decreases the required health. However, even if the room's positive value exceeds the health from the next step, the knight cannot have less than 1 health (max(1, ...)). Final Answer: After filling the DP table, the value in the top-left cell dp[0][0] is our answer as it represents the minimum
- Using this approach, we avoid recalculating the minimum health requirement for each cell multiple times, leading to an efficient algorithm with a time complexity of 0(m*n) where m and n are the dimensions of the dungeon grid.
- **Example Walkthrough**

[[-2, -3, 3],[-5, -10, 1]

1. Initialization of DP Table: We initialize dp with size (2+1)x(3+1) and fill it with inf except for the boundaries dp[2][2] and dp[2][3] or dp[3][2], which are set to 1.

3. Main Loop:

= 8.

dp = [[8, inf, inf, inf],

princess without dying.

Solution Implementation

from typing import List

return dp[0][0]

Example usage:

class Solution {

public:

sol = Solution()

def calculate_minimum_hp(self, dungeon: List[List[int]]) -> int:

dp = [[inf] * (num_columns + 1) for _ in range(num_rows + 1)]

 $dp[num_rows][num_columns - 1] = dp[num_rows - 1][num_columns] = 1$

Start from the bottom right corner and move to the top left corner.

Find the minimum HP needed to go to the next cell.

Cannot have less than 1 HP, hence the max with 1.

print(sol.calculate_minimum_hp([[-2, -3, 3], [-5, -10, 1], [10, 30, -5]]))

Initialize the cell to the princess's right and the one below her to 1.

for i in range(num_rows - 1, -1, -1): # Iterate over rows in reverse

for j in range(num_columns - 1, -1, -1): # Iterate over columns in reverse

 $min_hp_on_exit = min(dp[i + 1][j], dp[i][j + 1]) - dungeon[i][j]$

Return the HP needed at the start (0,0) to guarantee reaching the princess.

The hero needs at least 1 HP to reach the princess.

 $dp[i][j] = max(1, min_hp_on_exit)$

from math import inf

class Solution:

[6, 1, 1, 1],

[inf, inf, 1, inf]]

dp = [[inf, inf, inf, inf],

[inf, inf, inf, 1],

```
[inf, inf, 1, inf]]
```

```
of that room's demon value 3 minus 1 (minimum health needed to survive). Since 3 minus 1 is 2, and we need a maximum of 1, it stays as 1:
dp = [[inf, inf, inf, inf],
       [inf, inf, 1, 1],
        [inf, inf, 1, inf]]
```

2. **Boundary Conditions**: The bottom-right corner (m - 1, n - 1) is the princess's room, hence dp[1][2] will be the maximum of 1 and the inverse

○ We first calculate dp[1][1], which is the maximum of 1 and min(dp[1 + 1][1], dp[1][1 + 1]) - dungeon[1][1]. The minimum of dp[2][1]

○ Then we calculate dp[1][0] which is the maximum of 1 and min(dp[1 + 1][0], dp[1][0 + 1]) - dungeon[1][0]. The minimum of dp[2][0]

```
(inf) and dp[1][1][1] (1) is 1. With a dungeon value of -5, we get max(1, 1 - (-5)) = 6.
dp = [[inf, inf, inf, inf],
       [6, 1, 1, 1],
       [inf, inf, 1, inf]]
```

• For the top row, we repeat the same for dp[0][2] and dp[0][1]. Finally, dp[0][0] is computed, the maximum of 1 and min(dp[0 + 1][0], dp[0]

[0 + 1]) - dungeon [0] [0]. The minimum of dp [1] [0] (6) and dp [0] [1] (inf) is 6. Subtracting the dungeon value -2, we need max (1, 6 - (-2))

(inf) and dp[1][2](1) is 1. The dungeon value at [1][1] is -10. Thus 1(-10 + 10 = 0) becomes the value of dp[1][1].

```
Python
```

Now, the DP table shows dp[0][0] = 8, which means the knight needs at least 8 health points to ensure he can reach the

This simple example illustrates the backward calculation from the end goal, using dynamic programming to efficiently compute

the health needed at each step. The final answer as per the dp table shows that the knight needs a minimum starting health of 8.

Get the dimensions of the dungeon matrix. num_rows, num_columns = len(dungeon), len(dungeon[0]) # Initialize dp (Dynamic Programming) matrix with infinity. # An extra row and column are added to handle the edge cases easily.

```
Java
class Solution {
   // Function to calculate the minimum initial health needed to reach the bottom-right corner
    public int calculateMinimumHP(int[][] dungeon) {
       // Dimensions of the dungeon
       int rows = dungeon.length;
       int cols = dungeon[0].length;
       // Dynamic programming table where each cell represents the minimum health needed
        int[][] minHealth = new int[rows + 1][cols + 1];
       // Initialize the dp table with high values except the border cells right and below the dungeon
        for (int[] row : minHealth) {
            Arrays.fill(row, Integer.MAX_VALUE);
       // Initialization for the border cells where the hero can reach the princess with 1 health point
       minHealth[rows][cols - 1] = minHealth[rows - 1][cols] = 1;
       // Start from the bottom-right corner of the dungeon and move leftward and upward
        for (int i = rows - 1; i >= 0; --i) {
            for (int j = cols - 1; j >= 0; ---j) {
                // The health at the current cell is the minimum health needed from the next step minus the current cell's effect
               // It should be at least 1 for the hero to be alive
                int healthNeeded = Math.min(minHealth[i + 1][j], minHealth[i][j + 1]) - dungeon[i][j];
                minHealth[i][j] = Math.max(1, healthNeeded);
       // The result is the minimum health needed at the starting cell
       return minHealth[0][0];
C++
#include <vector>
#include <algorithm>
#include <cstring>
using std::vector;
using std::max;
using std::min;
using std::memset;
```

```
// We are also trying to find the lesser of the two paths to reach the next cell hence we use `min`.
               dp[i][j] = max(1, min(dp[i + 1][j], dp[i][j + 1]) - dungeon[i][j]);
       return dp[0][0]; // The minimum health needed at the start is at the top-left corner of the dp table.
};
TypeScript
// type definition for the 2D dungeon matrix
type Dungeon = number[][];
// Function to calculate the minimum health needed to reach the princess (at bottom-right of the dungeon)
// starting with positive health when moving only rightward or downward.
function calculateMinimumHP(dungeon: Dungeon): number {
   const m: number = dungeon.length;  // Number of rows
   const n: number = dungeon[0].length; // Number of columns
    let dp: number[][] = Array.from(Array(m + 1), () => new Array(n + 1).fill(0x3f3f3f3f)); // Create DP table filled with large
   // Set the health needed at the dungeon's exit. We need at least 1 health at the end.
   dp[m][n-1] = 1; // If at the last cell of the last row
```

// Loop through the dungeon starting from the bottom right corner, moving to the upper left corner

dp[i][j] = Math.max(1, Math.min(dp[i + 1][j], dp[i][j + 1]) - dungeon[i][j]);

 $min_hp_on_exit = min(dp[i + 1][j], dp[i][j + 1]) - dungeon[i][j]$

Return the HP needed at the start (0,0) to guarantee reaching the princess.

// Function to calculate the minimum health needed to reach the princess (at bottom-right of the dungeon)

// Initialize the dp array with a very large value, as we are looking for minimum health required.

// Loop through the dungeon starting from the bottom right corner, moving to the upper left corner

// The minimum health needed at the start of this cell is 1 or the health we need for the next cell

// minus the current cell value, whichever is larger. We are moving to the previous cell hence we use `max`.

// Set the health needed at the dungeon's exit. We need at least 1 health at the end.

// starting with positive health when moving only rightward or downward.

```

// The minimum health needed at the start of this cell is either 1 or the health we need for the next cell

// minus the current cell value, whichever is larger. We use `Math.max` to ensure we don't have non-positive health.

// We also want the smaller of the two possible paths (rightward or downward) to reach the next cell hence we use `Ma

```
Time and Space Complexity
 The given Python code implements a dynamic programming algorithm to calculate the minimum initial health required for a
```

return dp[0][0]

Example usage:

sol = Solution()

character to navigate a dungeon represented as a 2D grid where some cells contain positive values (health potions) and others contain negative values (traps). **Time Complexity**

The time complexity of the algorithm is 0(m*n), where m is the number of rows and n is the number of columns in the dungeon grid.

This is because the algorithm consists of a nested loop structure that iterates over each cell of the dungeon grid exactly once. **Space Complexity**

The space complexity is also 0(m*n) due to the auxiliary 2D list dp that has the same dimensions as the dungeon grid plus one extra row and column to handle the boundary cases. This dp list is used to store the minimum health required at each cell to reach the bottom right corner of the grid.
