383. Ransom Note

String Hash Table Counting Easy

Problem Description

The problem presents us with two strings: ransomNote and magazine. Our task is to determine if it's possible to construct the ransomNote string using the letters from the magazine string. There are certain rules to follow for this construction:

- Each letter in the magazine can be used only once.
- The order of the letters in the ransomNote does not have to match the order in the magazine.
- If all letters in the ransomNote can be matched to letters in magazine, taking into account the frequency of each letter, then the output should be true. • Conversely, if there are any letters in the ransomNote which appear more times than they do in the magazine, or if there are any letters in the
- ransomNote that don't appear in the magazine at all, the output should be false. Considering the above points, an immediate intuitive answer might seem complex since it implicitly involves tracking the count of

each character in both ransomNote and magazine. The heart of the problem lies in efficiently checking the availability of each character needed to form the ransomNote.

Intuition

letter. The key, intuitive insight here is the realization that if magazine contains all the letters required by ransomNote in the necessary quantities, then we should be able to "use up" these letters from the magazine without any shortage.

When considering the constraints of the problem, we naturally lean towards solutions that involve counting the frequency of each

The provided solution approach utilizes a hash table data structure, more specifically a Counter, which comes from Python's

Solution Approach

standard library collections. The hash table is particularly suited for this problem as it allows us to efficiently keep track of the counts of individual characters. Here is how the algorithm works step by step:

First, we initialize the hash table by passing the magazine string to the Counter, which will count the occurrences of each

- character in magazine and store them in the cnt hash table. Next, we iterate through each character c in the ransomNote string. For each such character, we perform two operations:
- We decrement the count of the character c in the hash table cnt. We check if the count of the character c falls below of after the decrement. If it does, it indicates that magazine does not have enough
 - occurrences of character c to match the requirements of ransomNote, and we return False. If we can iterate through all characters in ransomNote without the count of any character falling below 0, it implies that

magazine contains sufficient characters to construct ransomNote. Therefore, we return True.

Using the hash table for frequency counting is efficient as both insertion and lookup operations are on average O(1) complexity. The solution's overall time complexity is O(n+m), where n is the length of ransomNote and m is the length of magazine, since we

it's size depends on the size of the character set (which is fixed), not the size of the input. In this case, it is the 26 letters of the English alphabet, hence it is a constant space overhead. Using a Counter is particularly nifty here because it wraps up the necessary operations of initializing the frequency counts from

magazine, decrementing with each character from ransomNote, and performing the check for a negative amount in a concise and

have to iterate over both strings entirely. The space complexity is O(1) - even though we are using extra space for the hash table,

readable manner. This indicates a great example of choosing the right data structures to simplify the implementation of an algorithm. **Example Walkthrough**

Imagine the ransomNote is "aabbcc" and the magazine is "abccbaac". We want to know if we can construct the ransom note

Following the solution approach: We initialize the hash table cnt using Counter with the magazine string:

// The counter will have counts for letters as follows: {'a': 3, 'b': 2, 'c': 3}

cnt = Counter("abccbaac")

using the letters from the magazine.

Let's walk through a small example to illustrate the solution approach:

```
Next, we iterate through each character c in the ransomNote string "aabbcc" and update the hash table cnt:
• We take the first character 'a' from the ransomNote:
   Decrement the count of 'a' in cnt by 1: Counter({'a': 2, 'b': 2, 'c': 3})
```

- We take the second character 'a': ■ Decrement the count again: Counter({'a': 1, 'b': 2, 'c': 3})
 - We take the first 'b':

Count is not below 0, we move to the next character.

- Count is not below 0, we move to the next character.
- Decrement the count of 'b': Counter({'a': 1, 'b': 1, 'c': 3}) Count is not below 0, we move on.
- We take the second 'b': Decrement the count: Counter({'a': 1, 'b': 0, 'c': 3})

• We take the first 'c':

Solution Implementation

Python

Count is not below 0, so we continue.

- Decrement the count of 'c': Counter({'a': 1, 'b': 0, 'c': 2})
- Count is not below 0, move to the next character. We take the second 'c':
- Count is not below 0. Since we have gone through all the characters in ransomNote without any count falling below 0, we can conclude that it's

■ Decrement the count: Counter({'a': 1, 'b': 0, 'c': 1})

- possible to construct ransomNote from the magazine.
- then check against the characters required to form the ransom note.

This example illustrates how the solution approach uses Counter to efficiently manage character counts from the magazine, and

from collections import Counter

Check each character in the ransom note

Decrement the count for this character in the counter

If we haven't returned False, we can construct the ransom note

If count goes below zero, we cannot construct the note from the magazine

char_count = Counter(magazine)

char_count[char] -= 1

return False

return false;

int letterCount[26] = {};

for (char& letter : magazine) {

++letterCount[letter - 'a'];

for (char& letter : ransomNote) {

return true;

class Solution {

public:

// If all letters are accounted for, return true.

bool canConstruct(string ransomNote, string magazine) {

// Iterate through each character in the magazine

// Iterate through each character in the ransomNote

// Function to check if ransomNote can be constructed from magazine

// Create a frequency array for each letter in the alphabet

// Increase the count for the corresponding letter

// Decrease the count for the corresponding letter

// 'a' maps to index 0, 'b' to 1, ..., 'z' to 25

return True

if char count[char] < 0:</pre>

for char in ransom note:

Thus, the result for the example would be True.

class Solution: def canConstruct(self, ransom note: str, magazine: str) -> bool: # Create a counter object for all characters in the magazine

```
Java
class Solution {
    public boolean canConstruct(String ransomNote, String magazine) {
        // Array to count occurrences of each letter in the magazine.
        int[] letterCounts = new int[26];
        // Populate the letterCounts array with the count of each character in the magazine.
        for (int i = 0; i < magazine.length(); i++) {</pre>
            // Increment the count of the current character.
            letterCounts[magazine.charAt(i) - 'a']++;
        // Check if the ransom note can be constructed using the letters in the magazine.
        for (int i = 0; i < ransomNote.length(); i++) {</pre>
            // Decrement the count of the current character, as it is used in the ransom note.
            if (--letterCounts[ransomNote.charAt(i) - 'a'] < 0) {</pre>
                // If any letter in the ransom note is in deficit, return false.
```

```
if (--letterCount[letter - 'a'] < 0) {</pre>
                // If the count goes negative, magazine doesn't have enough of this letter
                return false;
        // If we've gone through the entire note without issues, the note can be constructed
        return true;
};
TypeScript
function canConstruct(ransomNote: string, magazine: string): boolean {
    // Initialize an array to keep track of the frequency of each letter in the magazine
    const letterCount = new Array(26).fill(0);
    // Iterate over each character in the 'magazine' string
    for (const char of magazine) {
        // Increment the count corresponding to the current character
        letterCount[char.charCodeAt(0) - 'a'.charCodeAt(0)]++;
    // Iterate over each character in the 'ransomNote' string
    for (const char of ransomNote) {
        // Get the index of the current character in 'letterCount' array
        // and decrement the frequency count of the corresponding character
        const index = char.charCodeAt(0) - 'a'.charCodeAt(0);
        letterCount[index]--;
        // If the frequency count goes negative, we do not have enough of this character in the magazine
        if (letterCount[index] < 0) {</pre>
```

```
from collections import Counter
```

return true;

return false;

```
class Solution:
   def canConstruct(self, ransom note: str, magazine: str) -> bool:
       # Create a counter object for all characters in the magazine
       char_count = Counter(magazine)
       # Check each character in the ransom note
       for char in ransom note:
           # Decrement the count for this character in the counter
           char count[char] -= 1
           # If count goes below zero, we cannot construct the note from the magazine
           if char count[char] < 0:</pre>
               return False
       # If we haven't returned False, we can construct the ransom note
       return True
Time and Space Complexity
  The time complexity of the function canConstruct is O(m + n), where m is the length of the ransomNote string and n is the
  length of the magazine string. This is because the function first counts the occurrences of each character in the magazine string,
```

// If we have not returned false by this point, it means we have enough characters for the ransomNote

complexity. The space complexity of the function is O(C), where C is the size of the character set involved in the magazine and ransom note. Given that these are likely to be letters from the English alphabet, the size of the character set C is 26. This fixed size of the character set means the space taken to store the counts is independent of the lengths of the input strings and is hence constant.

which takes 0(n) time, and then iterates through each character in the ransom note, which takes 0(m) time. Each character

decrement and comparison is an O(1) operation, thus the total time for the loop is O(m). Combined, it leads to O(m + n) time
