2097. Valid Arrangement of Pairs

Leetcode Link

Problem Description

Given a set of n nodes, there are n directed edges that form a sequence. The task is to find the correct arrangement of these edges to form the sequence. You are given a list pairs where pairs[i] = [a, b] indicates that there is a directed edge from node a to node b.

Return a list of pairs representing the correct arrangement of the edges. If there are multiple answers, return any of them.

Example:

Given pairs = [[1, 2], [2, 3], [3, 4], [4, 1]]

Output: [[1, 2], [2, 3], [3, 4], [4, 1]]

Approach

nodes.

we will first create a directed graph using the given node pairs. Then, we'll build the correct arrangement of the edges by starting at the unique node with an out-degree of 1 greater than its in-degree, or arbitrarily choosing a starting node if no such unique node exists.

The problem is a graph traversal problem, and we will be using Hierholzer's algorithm to find the valid arrangement. More specifically,

• We store the graph using an unordered_map with the node value as the key and stacks as the values to store the adjacent

We use the following key data structures:

- We use two unordered_maps to store the in-degree and out-degree of each node.
- Step 1: Create the directed graph

Step 3: Apply Hierholzer's algorithm to form the valid arrangement

Step 2: Find the starting node

We check for a unique node where the out-degree is one more than the in-degree. If such a node exists, we start from that node;

We first create the directed graph using the given node pairs. We also populate the in-degree and out-degree maps while doing this.

otherwise, we arbitarily choose a starting node from the given node pairs.

when there is no more unvisited edge from that node.

We start at the starting node and traverse the edges in a depth-first manner using recursion and keeping track of the visited edges. We also keep track of the visited edges by popping them from the stack once traversed, which means that the stack will be empty

Once all edges are visited, we reverse the order of the visited edges, representing the valid arrangement. We'll implement this algorithm in a class called Solution for the following languages: Python, Java, JavaScript, C++, and C#.

Python Solution

class Solution: def validArrangement(self, pairs):

2 python

```
ans = []
           graph = \{\}
           outDegree = {}
            inDegree = {}
 9
            for pair in pairs:
                start, end = pair
11
                if not start in graph:
12
                    graph[start] = []
13
                graph[start].append(end)
14
15
                outDegree[start] = outDegree.get(start, 0) + 1
                inDegree[end] = inDegree.get(end, 0) + 1
16
17
            startNode = self.getStartNode(graph, outDegree, inDegree, pairs)
18
19
            self.euler(graph, startNode, ans)
20
            ans.reverse()
21
            return ans
22
23
       def getStartNode(self, graph, outDegree, inDegree, pairs):
24
            for u in graph:
                if outDegree[u] - inDegree.get(u, 0) == 1:
25
26
                    return u
27
            return pairs[0][0]
28
29
       def euler(self, graph, u, ans):
30
            while graph[u]:
31
                v = graph[u].pop()
                self.euler(graph, v, ans)
                ans.append([u, v])

In this article, we have implemented the validArrangement function using Hierholzer's algorithm for the following languages: Python,

Java, JavaScript, C++, and C#. This function takes a list of directed node pairs called pairs and returns the correct arrangement of

the edges. We created the directed graph using the given node pairs and applied Hierholzer's algorithm to form the valid
