

Problem Description

The aim of the given problem is to compute the number of complete chess rounds played in an online tournament based on the login and logout times provided. Chess rounds commence every 15 minutes, starting from 00:00 and then at 00:15, 00:30, 00:45, and so on until 23:45. When a user logs in and logs out, we want to determine how many of these 15-minute rounds have fully passed.

A logoutTime is also provided, which represents the time the user logs out of the game.

A loginTime is given which represents the time the user logs in to the game.

- If the logoutTime is earlier than loginTime, this suggests the user played from loginTime through midnight to the next day, until
- logoutTime. A single chess round is counted only if the user is logged in for the entire duration of the 15-minute round. The task is to calculate

the number of such complete rounds played. For example, if the loginTime is 00:00 and logoutTime is 00:30, even though the user has been online for 30 minutes, they have

played only 2 full rounds (00:00 and 00:15), because they logout before the round starting at 00:30 could complete.

The solution approach involves a series of steps to compute the total number of complete rounds:

Intuition

1. Convert both loginTime and logoutTime to minutes. This simplification is done because working with minutes is easier than

- working with hours and minutes separately. It also helps to compare and perform arithmetic operations on the times effectively. 2. Account for the scenario when logoutTime is earlier than loginTime. This indicates that the user played through midnight. To
- 3. Rounds are started every 15 minutes, but we are only interested in complete rounds. Therefore, for the loginTime that is inbetween rounds, we need to round it up to the next round start time. On the other side, for the logoutTime, we need to round it down to the closest round start time that has been completed.

manage this, 24 hours (1440 minutes) are added to logoutTime to properly calculate the number of rounds.

- 4. Finally, the total number of complete rounds is the difference between the rounded times, divided by 15 (since each round is 15 minutes). We need to make sure not to count negative values in case logoutTime is right after loginTime, hence, we use max(0, finish - start).
- By rounding the loginTime and logoutTime to the closest round boundaries and then calculating the difference, we ensure that we're only counting the complete chess rounds.

Solution Approach

The code provided is a direct translation of this intuition. It uses simple arithmetic operations and logical reasoning to find the

solution without additional data structures or complicated algorithms, ensuring an efficient and clear solution to the problem.

The solution's implementation follows a direct and methodical approach, utilizing the built-in functions of the coding language and

1. A helper function named get is defined, which takes a string s representing time in the format "HH:MM" and converts this to the

basic arithmetic. Here's how the algorithm unfolds:

total number of minutes. It does so by multiplying the first two characters (hours) by 60 and adding to the last two characters (minutes), both of which are converted to integers.

- 2. The startTime and finishTime are then converted to minutes using the helper function get. 3. We then check if the startTime is greater than the finishTime. If it is, it means the player has played overnight, and therefore we add 24 hours (1440 minutes) to the finishTime.
- 4. Next, we handle the round start and end times. For the startTime (now in minutes), we round up to the nearest round start time

for this, ensuring that the minimum number of rounds returned is zero.

- by adding 14 minutes before dividing by 15 and multiplying by 15. This is because if the player logs in at any time within a round (e.g., 00:07 or 00:14), they miss that round and can only start playing in the next one. The division and multiplication discard the remainder if any, effectively rounding up to the next multiple of 15.
- 5. For the finishTime, we round down to the last complete round by simply dividing by 15. This is because if the player logs out anytime during a round, that round does not count as it is not completed. 6. The difference between the finish and start values gives us the total number of rounds. But, we must ensure that this number is

not negative, which is possible if the finishTime immediately follows the startTime. We use max(0, finish - start) to account

- The combination of helper function, careful addition for overnight sessions, and rounding the times to the nearest round boundaries are crucial in this implementation. There's no need for complex data structures; the entire solution leverages arithmetic operations to calculate the desired result.
- Example Walkthrough Let's go through a small example to illustrate the solution approach. Assume the following login and logout times:

Following the steps of the solution:

loginTime: 22:47

logoutTime: 01:12

1. Convert loginTime and logoutTime to minutes:

o get("22:47") would result in 22 * 60 + 47 = 1367 minutes. o get("01:12") would result in 1 * 60 + 12 = 72 minutes.

starts at 23:00.)

duration:

- 3. Round the times to the nearest chess round start times:
- For loginTime, rounded up to the next round: (1367 + 14) / 15 * 15 = 1380 minutes. (This corresponds to the round that

Difference in minutes: 1510 - 1380 = 130 minutes.

def convert_to_minutes(time_str: str) -> int:

Convert start and finish times to minutes

start_minutes = convert_to_minutes(start_time)

finish_minutes = convert_to_minutes(finish_time)

start_minutes_rounded = (start_minutes + 14) // 15

Calculate the number of complete 15-minute rounds

Ensure that it's not negative by using max(0, ...)

int hours = Integer.parseInt(time.substring(0, 2));

int minutes = Integer.parseInt(time.substring(3));

return hours * 60 + minutes;

function toMinutes(time: string): number {

input size, resulting in constant space complexity.

// Calculate the total minutes

return hours * 60 + minutes;

10

12

11 }

const [hours, minutes] = time.split(':').map(Number);

// Split the time string into hours and minutes and convert them into numbers

finish_minutes_rounded = finish_minutes // 15

Number of complete rounds: 130 / 15 = 8 full rounds.

Updated logoutTime in minutes: 72 + 1440 = 1512 minutes.

that starts at 01:00.) 4. Calculate the difference in rounded times and convert to the number of complete rounds:

For logoutTime, rounded down to the last complete round: 1512 / 15 * 15 = 1510 minutes. (This corresponds to the round)

2. Since logoutTime is on the next day (01:12 is after midnight), we add 1440 minutes (a full day) to logoutTime to get the correct

So, between 22:47 and 01:12 the next day, the user has played 8 complete chess rounds. We arrived at this conclusion by converting the given times into minutes, adjusting for overnight play, rounding the times to the nearest round boundaries, and computing the

difference. This example cleanly demonstrates the efficiency of the solution approach in evaluating the number of complete rounds.

Python Solution class Solution:

hours = int(time_str[:2]) # Extract hours and convert to integer

If start time is after finish time, assume finish time is the next day

The 14 is added before division to ensure proper rounding up for start time

minutes = int(time_str[3:]) # Extract minutes and convert to integer

def number_of_rounds(self, start_time: str, finish_time: str) -> int:

return hours * 60 + minutes # Return total minutes

and round finish time down to the previous 15-minute mark

Define a function to convert time from "HH:MM" format to minutes

```
if start_minutes > finish_minutes:
14
15
               finish_minutes += 24 * 60 # Add 24 hours in minutes
16
           # Round start time up to the next 15-minute mark
17
```

36
Time and Space Complexity
Time Complexity
The time complexity of the number of Rounds function is o(1). This is because the function consists of a few arithmetic operations and
```

format. Space Complexity

The space complexity of the number of Rounds function is also o(1). This function uses only a fixed number of integer variables to

store the start and finish times, and for the intermediate calculations. It does not allocate any additional space that grows with the

conditional checks, which are all constant time operations. The function calculates the minutes for the start and finish times, then

computes the rounds by dividing by 15. The constants do not scale with the size of the input, as the input is always a time in HH:MM
