Sorting

Problem Description

This problem asks for the length of the longest harmonious subsequence within an integer array nums. A harmonious array is defined as one where the difference between the maximum and the minimum values is exactly 1. It's important to note that a subsequence is different from a subset, as a subsequence maintains the original order of elements, and can be formed by removing zero or more elements from the array.

For example, given an array nums = [1,3,2,2,5,2,3,7], the longest harmonious subsequence is [3,2,2,2,3] with a length of 5.

Intuition

approach is to check for each element num, whether there exists an element num + 1 in the array. If it exists, then a harmonious subsequence can potentially be formed using the elements num and num + 1.

The solution to this problem leverages hashing to keep track of the frequency of each number in the given array. The essence of the

Since the elements need not be adjacent, we only care about the counts of the elements num and num + 1. We can find the total count of such pairs and keep updating the maximum found so far if the current count exceeds the previous maximum. Using a hash map or, in Python, a Counter object is ideal for this task as it allows us to efficiently store and access the frequencies of each element.

Create a frequency counter (hash map) from the array to count occurrences of each element.

Here's the intuitive breakdown of the process:

- Iterate through each element num in the array. 3. Check if there's an element num + 1 in the counter hashmap.
- 4. If so, calculate the sum of the count of num and num + 1 since those two form a harmonious sequence.
- 5. Compare this sum with the current longest harmonious subsequence length, and update it if this one is longer. Continue this process until you have checked all elements.
- 7. Return the longest length obtained.
- This approach is efficient because it eliminates the need to consider actual subsequences. Instead, it relies on counts, which

simplifies the process of verifying the harmonious condition.

Solution Approach

The implementation of the solution follows these steps:

1. Counter Data Structure: We use Python's Counter class from the collections module, which is a subclass of a dictionary. It is

if num + 1 is a key in the counter.

subsequence we've seen so far.

- used to count objects and store them as dictionary keys and their counts as dictionary value. Here it is used to build a hash map of each number (num) in nums array to its frequency. 2. Iterate Through Each Element: We iterate through each element in the nums array. For each element num, we are going to check
- 3. Check and Calculate: If num + 1 exists in our counter, we then know we can form a harmonious subsequence with num and num + 1, since our Counter contains the counts of all numbers and we only want the difference between numbers to be exactly 1. To
- calculate the length of this potential subsequence we add the count of num and the count of num + 1. 4. Maximize Answer: Now, having the sum of counts of num and num + 1, we compare it with our current answer (initially zero). If our sum is greater, we update the answer to this larger sum. Essentially, we are keeping track of the largest harmonious
- 5. Return the Result: Finally, after iterating over all the elements in the nums array, we end up with the length of the longest harmonious subsequence in the ans variable.

The algorithm uses O(N) space due to the counter, where N is the number of elements in the nums array. The time complexity is also

Here's the key part of the code explained: 1 counter = Counter(nums) # Step 1: Build the counter hash map 2 ans = 0

ans = max(ans, counter[num] + counter[num + 1]) # Step 4: Maximize the answer 6 return ans # Step 5: Return the result

for num in nums: # Step 2: Iterate through each element

harmonious subsequence involving the number 3.

longest_harmonious_subseq_length = 0

Iterate through each number in the nums list

if (frequencyMap.containsKey(num + 1)) {

return longestHarmoniousSubsequence;

Check if the number has a companion number that is one greater

if num + 1 in counter: # Step 3: Check if `num + 1` is present

```
This code snippet illustrates how we use the algorithms and data structures mentioned to find the length of the longest harmonious
subsequence.
```

O(N), since we iterate over the array once to build the counter and once again to find the ans.

Example Walkthrough Let's consider a small example to illustrate the solution approach with an array nums = [1, 1, 2, 2, 3].

1. First, we create a counter from the array. Our counter will look like this: {1: 2, 2: 2, 3: 1}, where each key is the element from

nums, and each value is how many times that element appears.

2. We now start to iterate through each element in nums. We take the first element 1 and check if 1 + 1 (which is 2) is a key in the

- counter. It is, so we find the sum of the counts of 1 and 2, which is 2 + 2 = 4. We compare this sum 4 with our current answer (which is o since we just started) and update the answer to 4.
- calculation would be the same, thus no change in the answer. 4. Next, we consider number 2. We check if 2 + 1 (which is 3) is a key in the counter. It is, so we find the sum of the counts of 2 and 3, which is 2 + 1 = 3. We compare this sum 3 with our current answer 4, and since 3 is less than 4, we don't update the answer.

3. We move to the next element, which is also 1. Since we've already considered this number and the counter hasn't changed, the

- 5. Then, we take the next 2, and just like the previous 2, it yields the same calculation, so no change occurs. 6. Finally, we consider the last element 3 and check for 3 + 1 (which is 4). This is not a key in the counter, so we don't have a
- 7. Having examined all the elements, we end up with the answer 4, which is the length of the longest harmonious subsequence [1, 1, 2, 2].

This example validates our solution approach: using a counter to efficiently compute the length of the longest harmonious

Python Solution

subsequence by only considering the frequencies of num and num + 1 for each number in the array. The final answer for this example

def findLHS(self, nums: List[int]) -> int: # Count the frequency of each number in the list using Counter frequency_map = Counter(nums) # Initialize the variable to store the length of the longest harmonious subsequence

```
if num + 1 in frequency map:
14
                   # Harmonious subsequence found with num and num + 1
15
                   # Calculate its length: count of num + count of num + 1
16
17
                    current_length = frequency_map[num] + frequency_map[num + 1]
                    # Update the answer with the maximum length found so far
18
```

class Solution:

// and the number that is one more than the current number

// Return the length of the longest harmonious subsequence found

// If it exists, calculate the sum of the frequencies of the current number

// Update the longest harmonious subsequence if the current sum is greater

longestHarmoniousSubsequence = Math.max(longestHarmoniousSubsequence, currentLength);

// Declare a HashMap to keep track of the frequency of each number in nums let frequencyMap: HashMap<number, number> = HashMap.empty();

Typescript Solution

// Importing necessary types from 'collections' module

import { HashMap } from "collectable";

```
// Function to find the length of the longest harmonious subsequence in the nums array
   function findLHS(nums: number[]): number {
       // Count the frequency of each number in the given nums array
       nums.forEach(num => {
           frequencyMap = HashMap.update<number, number>(n => (n || 0) + 1, num, frequencyMap);
       });
12
13
       let longestHarmoniousSequence: number = 0; // Variable to hold the length of the longest harmonious sequence
14
15
       // Iterate through the numbers in the map to find the longest harmonious sequence
16
       HashMap.forEach((count, num) => {
17
18
           // Check if there is a number in the map which is exactly one more than the current number
           if (HashMap.has(num + 1, frequencyMap))
19
               // If found, update the longestHarmoniousSequence with the larger value between the previous
20
               // longest and the total count of the current number and the number that is one more.
               const nextCount = HashMap.get(num + 1, frequencyMap) || 0;
23
               longestHarmoniousSequence = Math.max(longestHarmoniousSequence, count + nextCount);
24
       }, frequencyMap);
25
26
27
       // Return the length of the longest harmonious sequence found
       return longestHarmoniousSequence;
28
30
Time and Space Complexity
```

Time Complexity The function involves calculating the frequency of each number in the list, which can be done in O(n) time where n is the number of elements in nums. The for loop iterates through each element in nums once, and each lookup and update operation within the loop can be considered to have an average-case time complexity of 0(1) due to the hash table (dictionary) operations in Python.

space complexity of the function is O(n).

Therefore, the total time complexity of this function is O(n). Space Complexity

The space complexity comes from the use of a counter (essentially a hash table), which stores each unique number and its

corresponding frequency. In the worst case, if all elements in nums are unique, the space required would be O(n). Thus, the overall
