2012. Sum of Beauty in the Array

Leetcode Link

In this problem, we are provided with a 0-indexed integer array nums. We need to determine the "beauty" for each element nums [i] at

Problem Description

positions i from 1 to nums.length - 2, according to the following rules: • The beauty is 2 if nums [i] is greater than all preceding elements nums [j] where j < i, and less than all succeeding elements

- nums [k] where k > i. • The beauty is 1 if nums [i] is greater than the immediate preceding element nums [i - 1] and less than the immediate succeeding element nums [i + 1], but does not satisfy the condition for beauty 2.
- The beauty is 0 if none of the above conditions is satisfied.
- Our goal is to calculate the sum of beauty for all such nums [i].

minimum element observed from the end down to i + 1.

left of i and the minimum element to the right of i. This leads us to an efficient way to evaluate the beauty for each index.

Intuition

The approach is as follows: 1. Create two additional arrays, lmx and rmi, to record the maximum element observed from the beginning up to i - 1 and the

The solution builds on the key observation that to find the beauty of an index i, it suffices to determine the maximum element to the

3. Iterate through the nums array from right to left, populating rmi with the minimum value seen so far.

- 4. Now, traverse the array again and for each i (from 1 to nums.length 2), check the following: If lmx[i] < nums[i] < rmi[i], add 2 to the answer since nums[i] satisfies the condition for beauty 2.
- ∘ Else if nums[i 1] < nums[i] < nums[i + 1] and the first condition is not satisfied, add 1 to the answer, marking beauty 1.

2. Iterate through the nums array from left to right, populating lmx by recording the maximum value seen so far.

- 5. Sum the beauty values calculated for each i to get the final answer.
- Solution Approach

To implement the solution, we follow these steps, making use of sequential iterations and auxiliary space for the arrays needed to

keep track of maximum and minimum boundaries:

Calculate the length n of the array nums.

rmi[i] = min(rmi[i + 1], nums[i + 1]).

Initialize a variable ans to hold the sum of beauty scores.

Initialize two arrays lmx and rmi of size n to keep track of the left maximum and right minimum values, respectively. lmx[i]

1. Initialization:

will store the maximum value from the start of the array to index i - 1, and rmi[i] will store the minimum value from the end of the array to index i + 1. • lmx is initially filled with 0 because there is no number before the start of the array.

o rmi is filled with a very large number, 100001, to ensure that any real number in the array nums will be less than this

placeholder value. 2. Populate lmx: ○ Iterate through nums from left to right starting from index 1 up to n - 1. ∘ Update lmx[i] such that it holds the maximum value seen up to nums[i - 1]. This is done using the formula lmx[i] =

• Update rmi[i] such that it holds the minimum value seen from nums[i + 1] to the end of the array. The formula used here is

max(lmx[i-1], nums[i-1]).3. Populate rmi:

○ Iterate through nums from right to left starting from index n - 2 down to 0.

○ Iterate through the elements of nums from index 1 to n - 2 (inclusive).

• Check if the beauty of nums[i] is 2 by comparing if lmx[i] < nums[i] < rmi[i]. If this condition is true, increment ans by 2. Else if nums [i] does not qualify for a beauty of 2, check if it is greater than the element to its left and less than the element

4. Calculate the total beauty:

- to its right (i.e., check if nums[i 1] < nums[i] < nums[i + 1]). If true, increment ans by 1. If neither condition is satisfied, the beauty for that element is 0, so ans remains the same. 5. Return the result:
- The main data structures used in this solution are the arrays lmx and rmi for dynamic programming, which store computed values that can be used to determine the beauty of each element efficiently. The algorithm makes use of max() and min() functions for comparisons, and a single pass through the array (ignoring the separate passes for lmx and rmi initializations) to calculate the sum of

beauty. This approach ensures that we have all the necessary information to evaluate the beauty of each element without using

Let's walk through a small example to illustrate the solution approach. Consider the integer array nums = [1, 2, 3, 4, 2].

nested loops, which would result in a higher computational complexity. Example Walkthrough

After the loop completes, ans contains the sum of beauty for all nums[i], and we return this value.

• n = 5 (length of nums) Initialize lmx = [0, 0, 0, 0, 0] and rmi = [100001, 100001, 100001, 100001] Step 2: Populate Lmx Starting from i = 1, iterate to i = 4: \circ lmx[1] = max(0, nums[0]) = 1

Step 3: Populate rmi

 \circ lmx[2] = max(1, nums[1]) = 2

 \circ lmx[3] = max(2, nums[2]) = 3

 \circ lmx[4] = max(3, nums[3]) = 4

 \circ rmi[2] = min(2, nums[3]) = 2

o rmi[1] = min(2, nums[2]) = 2

o rmi[0] = min(2, nums[1]) = 2

Now rmi = [2, 2, 2, 2, 100001]

Step 4: Calculate the total beauty

 \circ For i = 2:

 \circ For i = 3:

Step 5: Return the result

• Now lmx = [0, 1, 2, 3, 4]

Step 1: Initialization

```
    Starting from i = 3, iterate to i = 0:

    \circ rmi[3] = min(100001, nums[4]) = 2
```

• nums [2] does not satisfy any beauty conditions, so ans stays the same.

• nums[3] is greater than both lmx[3] and rmi[3], so it adds nothing to ans.

The result, which is the sum of beauty for all nums [i], is 1. This is the final answer to the problem.

num_elements = len(nums) # Get the number of elements in the list

Loop through each element of the array except the first and last

 $max_left[i] = max(max_left[i - 1], nums[i - 1])$

min_right[i] = min(min_right[i + 1], nums[i + 1])

leftMax[i] = Math.max(leftMax[i - 1], nums[i - 1]);

rightMin[i] = Math.min(rightMin[i + 1], nums[i + 1]);

int totalBeauty = 0; // Variable to hold the total sum of beauty

 $else\ if\ (nums[i-1] < nums[i] & nums[i] < nums[i+1]) {$

// Loop through the array, omitting the first and last element

if (leftMax[i] < nums[i] && nums[i] < rightMin[i]) {</pre>

```
    Initialize ans = 0

• For i = 1 \text{ to } n - 2:
    \circ For i = 1:
         • lmx[1] is 1, nums[1] is 2, rmi[1] is 2.
         • nums[1] is greater than lmx[1] but not less than rmi[1], so check next condition.
         • nums[0] is 1, nums[1] is 2, nums[2] is 3. It satisfies nums[0] < nums[1] < nums[2], so add 1 to ans.</p>
```

• lmx[2] is 2, nums[2] is 3, rmi[2] is 2.

• lmx[3] is 3, nums[3] is 4, rmi[3] is 2.

def sumOfBeauties(self, nums: List[int]) -> int:

for i in range(num_elements -2, -1, -1):

for i in range(1, num_elements):

for (int i = 1; i < n; ++i) {

for (int i = n - 2; i >= 0; --i) {

for (int i = 1; i < n - 1; ++i) {

totalBeauty += 1;

return totalBeauty;

prefixMax[0] = nums[0];

postfixMin[n - 1] = nums[n - 1];

Typescript Solution

// Return the total beauty of the array.

function sumOfBeauties(nums: number[]): number {

return totalBeauty;

// Return the sum of beauty of all elements

The final value of ans after the loop is 1.

In this particular example, the only element to contribute to the beauty sum was nums [1] with a beauty of 1. **Python Solution**

Time and Space Complexity
Time Complexity
The given code consists of three separate for loops that are not nested. Each of these loops runs linearly with respect to the length
```

// Set the first element of prefix and the last element of postfix to be the corresponding values from 'nums'.

1 // Function to calculate the sum of beauties for all elements in the array except the first and last.

1. The first loop initializes the lmx array, which takes 0(n) time as it iterates from 1 to n-1. 2. The second loop initializes the rmi array, which also takes O(n) time as it iterates from n-2 to O(n)

+ O(n), which simplifies to O(n).

variables like n, i, and ans.

1. The lmx array uses O(n) space.

2. The rmi array also uses O(n) space.

of the input array nums, which is denoted as n.

3. The third loop calculates the ans (answer) by iterating once again in linear time over the range from 1 to n-1, resulting in O(n) time. When we add these up, since they are executed in sequence and not nested, the overall time complexity of the code is O(n) + O(n)

- Space Complexity The space complexity of the code is due to the additional arrays lmx and rmi that are both of length n, and the space used for
- Besides these arrays, only a constant amount of extra space is used for the loop indices and the ans variable. Thus, the total auxiliary space used by the algorithm is O(n) + O(n) which simplifies to O(n).

In conclusion, the time complexity of the algorithm is O(n) and the space complexity is O(n).
