2511. Maximum Enemy Forts That Can Be Captured

Problem Description

Array

Easy

Here's what they represent: A −1 means no fort is present at that position.

You are given an array forts which consists of integers representing the positions of forts. The integer values can be -1, 0, or 1.

- A 0 indicates an enemy fort is present at that position. • A 1 indicates a fort under your command is present at that position.

Two Pointers

Your objective is to move your army from one of your forts to an empty position. The conditions for the movement are:

You cannot pass over an empty position or a position with your fort during this move.

- The question asks you to calculate the maximum number of enemy forts you can capture during such a move. If it is not possible to move your army or you don't have any forts under your command, then the maximum number is 0.

Your army must travel over positions containing only enemy forts (denoted by 0).

Intuition

• Start from the first element, iterate through the array and search for a fort under your command (a 1 in the array).

between.

• If another fort under your command is found (another 1), then the number of enemy forts captured during this move would be the count of 0 s

command, and j is used to find the next fort under our command after capturing enemy forts.

traversal, increment j until a 0 is not encountered (either reach another 1 or -1).

Only sequences consisting solely of enemy forts (0) are considered for capturing.

Outer While Loop (Traverse forts): Begin loop from the first position.

 \circ Position $\mathbf{i} = \mathbf{0}$ has value 1, indicating a fort under your command.

Move the pointer i to position 3. Repeat for the next portion of the array.

 \circ At i = 4 (forts [4] = 1), we have a fort under our control once again.

 \circ In this sequence, we have captured j - i - 1 = 6 - 4 - 1 = 1 enemy fort.

Let's use a small example to illustrate the solution approach given the following array forts:

cannot move over an empty position. Therefore, no enemy forts were captured in this sequence.

found in between minus one (since we lose one position when we land on the second 1).

To solve this problem, we can perform a linear scan over the array forts with the following approach:

 Keep track of the maximum count found throughout the entire iteration. Continue this process until the end of the array is reached.

• Once a fort under your command is found, search for the next closest enemy fort (a 0), and keep counting the number of enemy forts in

- This algorithm efficiently computes the maximum number of enemy forts that can be captured because it accounts for all possible movements from each of your forts to any other eligible position in a single pass. By always choosing the move that
- captures the most forts, we ensure that we find the maximum possible value.

The provided solution uses a simple one-pass algorithm to iterate over the array of forts. We make use of a while loop that runs until the end of the array. There are two pointers used in the process: i and j. Pointer i is used to locate forts under our

Initialize two variables, i and ans, to 0. The variable i serves as a pointer to the current position in forts, and ans stores

Use a while loop to traverse the forts array from the current position identified by i until the end of the array (n is the

If the loop ends at a position j where forts[j] is 1, it means an enemy fort was captured. Thus, calculate the number of

the maximum number of enemy forts captured so far.

length of forts).

value of ans.

Here's a step-by-step approach to the solution:

Solution Approach

Inside the loop, initiate a nested while loop that starts with j = i + 1. The variable j scans forward to count enemy forts: If forts[i] is 1 (your fort), traverse through the array starting from i + 1 to find a subsequent 0 (enemy fort). During

- captured forts as j i 1. The -1 subtracts the position of the ending 1, which is not an enemy fort. Update the maximum number of enemy forts captured, $\frac{1}{2}$ ans, if the current count (j - i - 1) is greater than the previous
- scanned. This ensures no potential fort positions are skipped and that we consider all possibilities.

Finally, return the value of ans, which holds the maximum number of enemy forts captured in any possible move.

After processing from position i to j, move the pointer i to position j and continue the algorithm until all positions are

This simple algorithm is optimal because it ensures that: • Only forts under your command (1) are considered as the starting point for an invasion.

• The number of checks is the lowest possible, as we only care about streaks of enemy forts between your forts, achieving O(n) time complexity.

 \circ Moving ahead from position i = 0: We have forts[1] = 0, forts[2] = 0, and the next position forts[3] is -1, so we stop here since we

forts = [1, 0, 0, -1, 1, 0, 1]

 Move to i + 1, looking for consecutive enemy forts (0). **Capture Enemy Forts:**

Repeat the Process:

Example Walkthrough

 \circ Since forts[3] = -1, we move to i = 4.

With this array, follow the solution approach step by step:

Initialize Variables: Start with i = 0 and ans = 0.

Inner While Loop (Locate Next Fort):

 Move ahead: forts[5] = 0 is an enemy fort. \circ However, at j = 5 + 1 = 6, we reach forts[6] = 1, another fort under our control, and we stop.

• Start the inner loop from j = i + 1 = 5.

Update Maximum Captured Enemy Forts:

def captureForts(self, forts: List[int]) -> int:

n = len(forts) # Get the length of the forts list.

while i < n and forts[j] == 0:</pre>

which means they cancel each other out.

if i < n and forts[i] + forts[i] == 0:</pre>

ans = max(ans, j - i - 1)

// where the non-zero numbers sum up to zero.

// Length of the array representing forts.

// Index to iterate through forts array.

// Potential second fort index.

++nextFortIndex;

// Find the next non-zero fort.

const fortCount = forts.length: // Total number of forts

// Loop through the array of forts

while (currentIndex < fortCount) {</pre>

if (forts[currentIndex] !== 0) {

// Find the next non-zero fort

let currentIndex = 0; // Index to traverse the forts array

let maxDistance = 0; // This will hold the maximum distance between two forts

// Ensure the current fort is not zero (zero implies the fort has already been captured)

let nextIndex = currentIndex + 1; // Index for the next fort

while (nextIndex < fortCount && forts[nextIndex] === 0) {</pre>

// Check if current fort at index i is not a zero.

while (nextFortIndex < n && forts[nextFortIndex] == 0) {</pre>

// two non-zero forts is zero, implying opposite teams.

// Calculate the current number of zeroes.

maxZeroes = Math.max(maxZeroes, zeroCount);

int zeroCount = nextFortIndex - i - 1;

if (nextFortIndex < n && forts[i] + forts[nextFortIndex] == 0) {</pre>

// Update maximum zeroes if the current count exceeds it.

int nextFortIndex = i + 1;

public int captureForts(int[] forts) {

int n = forts.length;

// Iterate over the array.

if (forts[i] != 0) {

int maxZeroes = 0;

int i = 0;

while (i < n) {

i = ans = 0 # Initialize pointer i to 0 and answer 'ans' to 0.

- Update ans to the maximum of itself and the current count: ans = max(ans, 1). • Now, ans = 1.
- **Continue Until the End:** Move i to j = 6 and continue, but we're already at the end of the array.

Conclude with Results:

Solution Implementation

if forts[i]:

i = j

class Solution {

i += 1

Python

class Solution:

- can capture in one move, which is 1 for this particular array.
- # Iterate through the list of forts. while i < n: j = i + 1 # Set the pointer j to the next position after i. # If the current fort at position i is a friendly fort (non-zero).

Find the next friendly fort (non-zero) starting from position j.

If such a fort is found and the sum of the values at i and j is 0,

and update the answer 'ans' if this distance is greater.

Move the starting pointer i to the position of j for the next iteration.

// Method to find the maximum number of zeroes between two non-zero numbers in an array,

// This will hold the final answer: the maximum number of zeroes between capturing forts.

// Check if the end of the array hasn't been reached and if the sum of the

 \circ Having traversed the entire array, ans = 1 is the maximum number of enemy forts we can capture during a move.

This example shows that with the given solution approach, we can calculate the maximum number of enemy forts that the army

Return the maximum number of captured forts. return ans Java

Calculate the distance between the forts, excluding the start and end points,

```
// Move to the next potential fort.
            i = nextFortIndex;
        // Return the maximum number of zeroes between two capturing forts.
        return maxZeroes;

        return ans
Time and Space Complexity
```

The provided Python function captureForts calculates the maximum distance between pairs of forts, with the condition that the

The time complexity of the function is O(n), where n is the length of the forts list. This is because the function iterates through the list only once with a single while-loop. Within the while-loop, the inner while-loop also iterates through portions of the list, but

sum of the strengths of a pair of forts is zero, and there are only zeroes between them.

size of the input, hence the linear time complexity.

Time Complexity:

Space Complexity: The space complexity is 0(1) since there are only a constant number of variables used (n, i, j, ans) that do not depend on the size of the input list. No additional space that grows with the input size is allocated during the execution of the function.

overall each element is visited at most once by either the outer or the inner loop. There are no nested loops that depend on the
