1143. Longest Common Subsequence

Problem Description

A **subsequence** is defined as a sequence that can be derived from another sequence by deleting some elements without changing the order of the remaining elements. A **common subsequence** means a sequence that exists in both strings.

In this LeetCode problem, we are dealing with finding the longest common subsequence between two strings text1 and text2.

The challenge is to determine the length of the longest sequence that exists in both text1 and text2. If there is no such sequence, then the result should be 0.

original strings). Subsequences are more forgiving as they are not bound by the need for continuity.

The task is not to be confused with finding common substrings (which are required to occupy consecutive positions within the

The solution leverages **Dynamic Programming (DP)**, a method for solving complex problems by breaking them down into simpler

Intuition

To approach this, we create a 2D array, f, with dimensions $(m+1) \times (n+1)$, where m and n are the lengths of text1 and text2, respectively. The value of f[i][j] will hold the length of the longest common subsequence between the first i characters of

subproblems. The idea is to build up a solution using previously computed results for smaller problems.

text1 and the first j characters of text2.

We iterate over both strings and fill this table based on the following rules:

• If the characters at the current position in both strings match, then the longest common subsequence would be that of the previous characters

If the characters do not match, we take the maximum of two possible cases:

of both strings plus one (because we include this matching character).

The <u>dynamic programming</u> algorithm follows these steps:

Including one less character from text1 and the current number of characters from text2.
 Including the current number of characters from text1 and one less from text2.

The final answer, the length of the longest common subsequence, will be the value stored in f[m][n] after the entire table is

filled.

Solution Approach

The implemented solution uses a two-dimensional <u>dynamic programming</u> table f to store the lengths of longest common

subsequences for different parts of text1 and text2. The structure of f makes it easy to build the solution incrementally. Each

entry f[i][j] in this table represents the length of the longest common subsequence between the first i characters of text1

and the first j characters of text2.

Initialize a 2D array f with (m + 1) rows and (n + 1) columns to 0, where m is the length of text1 and n is the length of text2. The extra row and column are used to handle the base case where one of the strings is of length 0, which naturally results in a common subsequence of length 0.
 Iterate over the rows of the array (corresponding to each character in text1) and the columns (corresponding to each

[j - 1] + 1. This step follows from the fact that if the current characters match, the longest common subsequence would extend from the longest subsequence obtained without including these characters, hence we add 1.

At each (i, j) position, check if characters text1[i - 1] and text2[j - 1] are equal. If they are, set f[i][j] = f[i - 1]

If the characters at text1[i - 1] and text2[j - 1] aren't equal, we have to choose the longer subsequence that we could

obtain by either discarding the current character from text1 or text2. Thus we set f[i][j] = max(f[i - 1][j], f[i][j -

character in text2), starting from index 1 to include the first character from each string.

- 1]).5. After completing the iteration process, the value f[m] [n] gives the length of the longest common subsequence of text1 and text2.
- subsequences of length 0 or 1) and use their solutions to build up to the answer for the entire sequence. The choice between when to add + 1 to the subsequence length or when to take the maximum of two choices is determined by the match between characters.

The beauty of this approach lies in its efficiency and the fact that it guarantees the optimal solution by systematically exploring all

possibilities and making the optimal choice at each step, based on the choices made in the previous steps.

ASCII value from each string: text1 'a'=97, 'b'=98, etc.; text2 'a'=97, 'c'=99, 'e'=101.

The process repeats. At i = 3, j = 2, 'c' matches 'c', so f[3][2] = f[2][1] + 1 = 2.

This algorithm uses dynamic programming's bottom-up approach, where we start by solving the smallest subproblems (i.e.,

Example Walkthrough

Let's take a small example with text1 = "abcde" and text2 = "ace". Here, we want to find the length of the longest common

. We initialize a 2D array f with dimensions (5 + 1) x (3 + 1) to 0, resulting in a table with 6 rows and 4 columns. Initially, the table is filled with zeros. The extra row and column act as base cases for subproblems where one of the strings is empty.

We start iterating from i = 1 to 5 (for text1) and j = 1 to 3 (for text2). For understanding, let's describe each character's

3. When i = 1 and j = 1, we compare text1[i - 1] (which is 'a') with text2[j - 1] (which is also 'a'). Since they match, we

remains 1.

subsequence between these two strings.

longest common subsequence of text1 and text2.

Get the lengths of both input strings

return dp_matrix[len_text1][len_text2]

len text1, len text2 = len(text1), len(text2)

def longestCommonSubsequence(self, text1: str, text2: str) -> int:

The array has (len text1 + 1) rows and (len text2 + 1) columns

 $dp_{matrix}[i][j] = dp_{matrix}[i - 1][j - 1] + 1$

// Function to find the length of the longest common subsequence in two strings.

// Create a 2D array to store lengths of common subsequence at each index.

// If current characters match, add 1 to the length of the sequence

// If current characters do not match, take the maximum length

// achieved by either skipping the current character of text1 or text2.

int longestCommonSubsequence(string text1, string text2) {

// Loop through both strings and fill the dp array.

if (text1[i - 1] == text2[i - 1]) {

dp[i][j] = dp[i - 1][j - 1] + 1;

for (int i = 1; i <= text2Length; ++i) {</pre>

int dp[text1Length + 1][text2Length + 1];

for (int i = 1; i <= text1Length; ++i) {</pre>

// Initialize the 2D array with zero.

return dp[text1Length][text2Length];

memset(dp, 0, sizeof dp);

} else {

int text1Length = text1.size(), text2Length = text2.size();

// until the previous character from both strings.

dp[i][j] = max(dp[i - 1][j], dp[i][j - 1]);

// Return the value in the bottom-right cell which contains the

const text1Length = text1.length; // length of the first input text

const text2Length = text2.length; // length of the second input text

If the characters match, take the diagonal value and add 1

 $dp_matrix[i][j] = max(dp_matrix[i - 1][j], dp_matrix[i][j - 1])$

between two strings, text1 and text2. Here is an analysis of its time and space complexities:

 $dp_{matrix}[i][j] = dp_{matrix}[i - 1][j - 1] + 1$

if text1[i - 1] == text2[i - 1]:

because it is proportional to the product of the two lengths.

// length of the longest common subsequence for the entire strings.

 $dp_matrix[i][j] = max(dp_matrix[i - 1][j], dp_matrix[i][j - 1])$

The bottom-right value in the matrix contains the length of the longest common subsequence

Initialize a 2D array (list of lists) with zeros for dynamic programming

set f[i][j] to f[i - 1][j - 1] + 1. Thus f[1][1] = f[0][0] + 1 = 1.

4. We continue this process. When i = 2 and j = 1, the characters text1[i - 1] (which is 'b') and text2[j - 1] (which is 'a') do not match. We compare f[i - 1][j] and f[i][j - 1] (both are 1), and take the maximum, which is 1. So f[2][1]

- After iterating through all the characters, the table f would look like this:

 0 0 0 0
- 0 1 2 36. The last cell f[5][3] contains the value 3, which is the length of the longest common subsequence of text1 and text2. This sequence can

be read off from the table by tracing back the cells that gave rise to the maximum values. In this case, the sequence is "ace" which is indeed the

the longest common subsequence. Starting from small subproblems, it builds up the solution to the entire problem, ensuring that all possibilities are considered and the most optimal decision is made at every step.

This example walkthrough illustrates how dynamic programming methodically fills out the 2D table to come up with the length of

dp_matrix = [[0] * (len_text2 + 1) for _ in range(len_text1 + 1)]

Loop through each character index of text1 and text2
for i in range(1, len text1 + 1):
 for i in range(1, len text2 + 1):
 # If the characters match, take the diagonal value and add 1
 if text1[i - 1] == text2[i - 1]:

If the characters do not match, take the maximum of the value from the left and above

```
class Solution {
   public int longestCommonSubsequence(String text1, String text2) {
      // Lengths of the input strings
      int length1 = text1.length();
      int length2 = text2.length();
}
```

else:

// Defines a function that computes the length of the longest common subsequence
// between two strings, 'text1' and 'text2'.
function longestCommonSubsequence(text1: string, text2: string): number {
```

};

```
// Create a 2D array 'dp' (for Dynamic Programming) to store lengths of
   // subsequences. +1 is for the base case where one of the strings is empty.
   const dp: number[][] = Array.from({ length: text1Length + 1 }, () => Array(text2Length + 1).fill(0));
   // Populate the 'dp' array
   for (let i = 1; i <= text1Length; i++) {</pre>
        for (let i = 1; i <= text2Length; i++) {</pre>
            // Check if the current character of 'text1' matches with the current
            // character of 'text2'
            if (text1[i - 1] === text2[i - 1]) {
                // If there's a match, increment the length of the subsequence
               // considering characters up to i and j are part of the subsequence
               dp[i][j] = dp[i - 1][j - 1] + 1;
            } else {
               // If there's no match, take the maximum length from either
               // excluding the current character of 'text1' or 'text2'
               dp[i][j] = Math.max(dp[i - 1][j], dp[i][j - 1]);
   // The bottom-right value in 'dp' matrix contains the length of the longest
   // common subsequence of 'text1' and 'text2'
   return dp[text1Length][text2Length];
class Solution:
   def longestCommonSubsequence(self, text1: str, text2: str) -> int:
       # Get the lengths of both input strings
        len_text1, len_text2 = len(text1), len(text2)
       # Initialize a 2D array (list of lists) with zeros for dynamic programming
       # The array has (len text1 + 1) rows and (len text2 + 1) columns
       dp_matrix = [[0] * (len_text2 + 1) for _ in range(len_text1 + 1)]
       # Loop through each character index of text1 and text2
       for i in range(1, len text1 + 1):
            for i in range(1, len text2 + 1):
```

The bottom-right value in the matrix contains the length of the longest common subsequence return dp_matrix[len_text1][len_text2]

else:

Time and Space Complexity

The given code defines a function longestCommonSubsequence that calculates the length of the longest common subsequence

If the characters do not match, take the maximum of the value from the left and above

- **Time Complexity:** The function uses two nested loops that iterate over the lengths of text1 and text2. Each cell f[i][j] is computed only once and in constant time. Therefore, the total number of operations is proportional to the product of the lengths of the two strings. This results in a time complexity of 0(m * n) where m is the length of text1 and n is the length of text2.
- text2. • Space Complexity: Space is allocated for a 2D list f with (m + 1) * (n + 1) elements, where each element takes up constant space. Considering m and n as the lengths of text1 and text2 respectively, the space complexity is 0(m * n),
