2600. K Items With the Maximum Sum

Problem Description

In this LeetCode challenge, we are dealing with a theoretical bag full of items, each marked with a number: 1, 0, or -1. We're given specific counts for each type of number, which are:

- numOnes: the count of items with 1 written.
- numZeros: the count of items with 0 written.

• numNegOnes: the count of items with -1 written.

Our goal is to choose exactly k items from the bag such that the sum of numbers on those chosen items is maximized. The

problem asks us to find out what that maximum sum could be. It's worth noting that because 0s do not contribute to the sum, they only affect our ability to reach the exact count of k items

without altering the sum. Also, adding -1s would decrease the sum, and so we would only want to add -1s if we have to reach k items and have no other options.

For the given solution approach, here's the intuition:

ntuition

If we have enough 1s to fill our quota of k items, then we can simply take k items all of which are 1s. This gives us the highest

as many of them as possible.

- possible sum, which is k (since each item adds 1 to the sum). If we don't have enough 1s, we must use 0s and possibly -1s to reach k total items. The 0s don't affect the sum, so we'll pick
- Once we've exhausted the 1s and 0s, if we still haven't reached the k items, we have no choice but to include -1 items. Each -1 item we include will decrease our sum by 1.
- In code:

• We first check if num0nes >= k. If yes, we just return k because we can fill our selection with just 1s and that would give us the maximum sum possible.

• When numOnes is not enough, we add in 0s to reach k. If numZeros >= k - numOnes, we can fill the rest with 0s. Hence, the sum will be just numOnes.

• If we still haven't reached k items after using all the 1s and 0s, we must use -1s. Here, we subtract the deficit from num0nes, which represents

having to use (k - num0nes - numZeros) negative ones.

The solution provided uses a simple conditional logic, which involves no complex algorithms or data structures. It is a

Therefore, the trick to solving this problem lies in understanding that 1s add to the sum, 0s don't affect the sum, and -1s subtract from the sum—and you always want to minimize the number of -1s you're forced to choose.

Solution Approach

straightforward iterative approach based on the business rules outlined by the problem statement. Let's break down the solution approach provided:

them. This is because 1 contributes to the highest possible individual value for an item in the bag. The sum here is the maximum we can obtain, which is simply the value k because taking k ones will give us a sum of k. When num0nes is not enough, numZeros >= k - num0nes: The second condition kicks in if we don't have enough ones to reach

When numOnes >= k: This is the simplest case. If we have equal or more than k items with 1 written on them, we take k of

k. We'll then use zeros to fill the remaining spots as they do not detract from the sum. If we have enough zeros to fill the remaining spots up to k, the sum remains num0nes. This is because 0 has no effect on the cumulative sum. When we need to use -1s, numZeros + numOnes < k: In the case where even our zeros are exhausted, and we haven't reached

the count of k, we are forced to use items with -1. The count of -1s used is (k - num0nes - numZeros), and as each -1

numZeros) which would be less than numOnes by exactly as many -1s as we had to include. The patterns used in the solution are: **Greedy** approach: By always taking 1s where possible, the solution aligns with greedy algorithms' principle of making the

Conditional branching: Using simple if-else logic helps navigate through the decisions based on the business rules defined.

subtracts 1 from the sum, we deduct this number from num0nes. This scenario gives us a sum of num0nes - (k - num0nes -

The solution is efficient and effective due to the simplicity of the problem—it's a problem that doesn't require optimization

techniques or complex data structures, as it boils down to elementary arithmetic operations driven by a few if-else statements. The time complexity here is O(1), meaning it requires a constant time to run, regardless of the values of num0nes, numZeros,

locally optimal choice at each stage with the hope of finding a global optimum.

numNegOnes, or k. This is because there are no loops or recursive calls in the code.

Example Walkthrough Let's suppose we have the following counts of items marked with 1, 0, and -1, and we want to maximize the sum by choosing k items: • num0nes = 4 (items with 1)

numNeg0nes = 2 (items with −1) • k = 6 (number of items to choose)

-1s.

class Solution:

• numZeros = 3 (items with 0)

We want to choose k=6 items to maximize the sum. Let's apply the solution approach:

numOnes = 6 - 4 = 2 and numZeros >= 2. Hence, we can fill up to k using all 1s and some 0s without needing to use any -1s.

1. The first check is whether we have enough 1s to fulfill the k items. Here, num0nes (4) is less than k (6), so we don't have

- enough 1s. Since we don't have enough 1s, we look at 0s. We have numZeros = 3, which is more than we need to top up to k because k -
- The sum is determined by the 1s we can use because 0s do not contribute to the sum. We have num0nes = 4 1s, and we are using 4 1s and 2 0s (since we need 6 items and we take as many 1s as available and the rest are 0s). After choosing 4 1s and 2 0s, the sum of the chosen items is 4 because 0s do not contribute, and we have avoided using any
- Solution Implementation **Python**

def kItemsWithMaximumSum(self, num_positives: int, num_zeros: int, num_negatives: int, target_count: int) -> int:

considering there are 'num_positives' +1s, 'num_zeros' 0s, and 'num_negatives' -1s. # If the number of +1s is greater than or equal to the target count k, # the maximum sum we can get is k (since +1 contributes the maximum to the sum).

If we run out of +1s and 0s, we will have to include -1s to reach the target count.

Each -1 will reduce the sum by 1. Therefore, we subtract the count of extra -1s needed

The function calculates the maximum sum of 'target_count' items

return num_positives - (target_count - num_positives - num_zeros)

// Function to calculate the maximum sum of 'k' elements from a set containing

// If the count of positive numbers (1's) is greater than or equal to k,

// we can take all k items as 1's to get the maximum sum which is k.

// which is the total count minus the count of positives and zeros.

return num_positives - (k - num_positives - num_zeros);

// 'num_positives' number of 1's, 'num_zeros' number of 0's, and 'num_negatives' number of -1's

int kItemsWithMaximumSum(int num_positives, int num_zeros, int num_negatives, int k) {

// If the count of zeros and positives combined is enough to fill all k items,

// If we don't have enough zeros to fill the gap between the number of positives

// and k, we will have to include negative numbers which reduce the overall sum.

// The maximum sum in this case is reduced by the number of negatives that are used,

// no negatives will be included, so the sum is just the number of positive numbers.

Therefore, the maximum sum we can achieve by choosing k=6 items from this bag is 4.

Thus, we can ignore -1s, given they will decrease our sum.

```
# If we don't have enough +1s, we can include all the +1s and then complement them with 0s.
# Since 0s do not contribute to the sum, if the remaining number (k - number of +1s) is less than
# or equal to the number of 0s, we can fill the rest with 0s. The sum remains equal to the count of +1s.
if num_zeros >= target_count - num_positives:
```

if num_positives >= target_count:

return target_count

return num_positives

from the total number of +1s we had.

```
# Example usage:
# Create a Solution object
solution = Solution()
# Call the method with a hypothetical case
max_sum = solution.kItemsWithMaximumSum(4, 2, 3, 5)
print(max_sum) # Expected output: 4
Java
class Solution {
    // Function to find the maximum sum of k items consisting of 1s, 0s, and -1s.
    public int kItemsWithMaximumSum(int numOnes, int numZeros, int numNegOnes, int k) {
        // If the count of 1s is itself greater than or equal to k, then the sum is k
        // since selecting k 1s gives you the maximum sum.
        if (numOnes >= k) {
            return k;
        // If after selecting all 1s, the count of 0s is enough to reach k,
        // we return the count of 1s because adding 0s does not change the sum.
        if (numZeros >= (k - numOnes)) {
            return numOnes;
        // If there aren't enough 1s and 0s to reach k, then we have to include some -1s.
        // Every -1 included will reduce the sum by 1. Hence, we subtract the number
        // of -1s to be included from the count of 1s to get the final sum.
        return numOnes - (k - numOnes - numZeros);

# from the total number of +1s we had.
return num_positives - (target_count - num_positives - num_zeros)
```

The function calculates the maximum sum of 'target_count' items

If the number of +1s is greater than or equal to the target count k,

considering there are 'num_positives' +1s, 'num_zeros' 0s, and 'num_negatives' -1s.

If we don't have enough +1s, we can include all the +1s and then complement them with 0s.

Since 0s do not contribute to the sum, if the remaining number $(k - number \ of +1s)$ is less than

or equal to the number of 0s, we can fill the rest with 0s. The sum remains equal to the count of +1s.

the maximum sum we can get is k (since +1 contributes the maximum to the sum).

Time and Space Complexity

print(max_sum) # Expected output: 4

Call the method with a hypothetical case

max sum = solution.kItemsWithMaximumSum(4, 2, 3, 5)

if num_positives >= target_count:

return target_count

The time complexity of the given code snippet is 0(1). This is because all operations in the kItemsWithMaximumSum method consist

Time Complexity

Example usage:

solution = Solution()

Create a Solution object

of simple arithmetic comparisons and subtractions which are performed in constant time, regardless of the input sizes of num0nes, numZeros, numNegOnes, and k. **Space Complexity**

The space complexity of the code is also 0(1). The function only uses a fixed amount of extra space for a few integer variables to hold the inputs and perform computations. There are no data structures like arrays or lists that would grow with the size of the input; therefore, the amount of space used does not scale with the input size.
