## 2482. Difference Between Ones and Zeros in Row and Column

**Problem Description** 

In this LeetCode problem, we're tasked with creating a difference matrix diff from a given binary matrix grid. The grid is a matrix composed of 0s and 1s with m rows and n columns, and both matrices are 0-indexed, which means that counting starts from the top-

**Leetcode Link** 

To construct the diff matrix, we follow these steps for each cell at position (i, j):

1. Calculate the total number of 1s (onesRow\_i) in the ith row. 2. Calculate the total number of 1s (onesCol\_j) in the jth column.

3. Calculate the total number of 0s (zerosRow\_i) in the ith row.

we increase the count for the respective row and column.

- 4. Calculate the total number of 0s (zerosCol\_j) in the jth column.
- 5. Set diff[i][j] to the sum of onesRow\_i and onesCol\_j subtracted by the sum of zerosRow\_i and zerosCol\_j.
- Our goal is to return the diff matrix after performing these calculations for every cell in the grid.

The intuition behind the solution is to use a straightforward approach by first calculating the sum of 1s in every row and column and

### storing them in two separate lists, rows and cols. This can be done by iterating over each element of the grid. If we encounter a 1,

left cell (0,0).

Once we have the sums of 1s for all rows and columns, we can calculate the difference matrix diff. For each cell in diff[i][j], we want to add the number of 1s in the ith row and jth column, and then subtract the number of 0s in the ith row and jth column. However, we can cleverly calculate the number of 0s by subtracting the number of 1s from the total number of elements in the row or

For example, to get the number of 0s in the ith row, we subtract the number of 1s in that row from the total number of columns n (because each row has n elements), which gives us  $zerosRow_i = n - onesRow_i$ . Similarly, we get  $zerosCol_j = m - onesCol_j$ .

column because the row sum of ones and zeros will always equal the total number of elements in that row or column.

The final diff matrix value at diff[i][j] is then computed as onesRow\_i + onesCol\_j - zerosRow\_i - zerosCol\_j, which simplifies to r + c - (n - r) - (m - c) when plugging in the sums and the number of 0s. This computation is performed for all cells (i, j) in

**Solution Approach** 

The implementation involves two main parts: first, computing the sum of 1s for each row and column; second, using these sums to

## each row and column. Initialize them with zeros as we haven't started counting yet.

calculate the diff matrix.

2. Iterate over each cell in grid using nested loops. For each cell (i, j), if the cell value is 1 (v in the code), increment rows [i] and cols[j] by 1. This loop runs through every element, ensuring that rows and cols accurately represent the number of 1s in their respective rows and columns.

3. After completing the sum of 1s, we initialize the diff matrix with zeros, creating an m by n matrix using list comprehension.

1. Initialize two lists rows and cols with length m and n, respectively, filled with zeros. These lists will keep track of the sum of 1s in

Let's break down the implementation step by step:

the grid to obtain the complete diff matrix.

- 4. Now we iterate over each cell in the diff matrix. For every pair (i, j), we calculate the value of diff[i][j] using the sums obtained previously. As derived before, the difference r + c - (n - r) - (m - c) simplifies to 2 \* (r + c) - m - n. This is because subtracting the zeros is the same as subtracting m or n and then adding back the number of ones in row r and column c.
- In terms of algorithms and patterns, the solution uses a simple brute-force approach which runs in O(m\*n) time because it requires iterating over all elements of the initial matrix to compute the sums, and then once more to compute the diff matrix.

additional complex data structures or algorithms are needed, making the implementation both straightforward and efficient for the

The data structures are simple lists for tracking the sums of ones in rows and columns, and a 2D list for the diff matrix. No

5. The previous calculation is applied to all elements in the diff matrix by iterating through the ranges of m for rows and n for

columns. This modifies the diff matrix to contain the correct difference values per the problem's definition.

**Example Walkthrough** 

Let's consider a small example to illustrate the solution approach with a binary grid of size  $m \times n$  where m = 2 and n = 3:

We are expected to create the diff matrix following the steps described in the content. Here's the step-by-step breakdown: 1. Initialize two lists rows and cols with m and n zeros respectively, where m is the number of rows and n is the number of columns:

## cols = [0, 0, 0] (for 3 columns)

rows = [0, 0] (for 2 rows)

For cell (0, 1), grid[0][1] = 0, no increments.

For cell (1, 2), grid[1][2] = 0, no increments.

The diff matrix after setting the values is:

1 diff = [

[4, 4, 4],

problem at hand.

1 grid = [

[0, 1, 0]

• For cell (0, 2), grid[0][2] = 1, increment rows[0] and cols[2]: rows = [2, 0], cols = [1, 0, 1] For cell (1, 0), grid[1][0] = 0, no increments.

```
2 [0, 0, 0],
       [0, 0, 0]
4. Next, iterate over each cell (i, j) in the diff matrix to calculate its value:
    • For cell (0, 0), diff [0][0] = 2 * (rows[0] + cols[0]) - m - n = 2 * (2 + 1) - 2 - 3 = 4
    \circ For cell (0, 1), diff[0][1] = 2 * (rows[0] + cols[1]) - m - n = 2 * (2 + 1) - 2 - 3 = 4
    • For cell (0, 2), diff[0][2] = 2 * (rows[0] + cols[2]) - m - n = 2 * (2 + 1) - 2 - 3 = 4
```

• For cell (1, 0), diff[1][0] = 2 \* (rows[1] + cols[0]) - m - n = 2 \* (1 + 1) - 2 - 3 = 0

• For cell (1, 1), diff[1][1] = 2 \* (rows[1] + cols[1]) - m - n = 2 \* (1 + 1) - 2 - 3 = 0

 $\circ$  For cell (1, 2), diff[1][2] = 2 \* (rows[1] + cols[2]) - m - n = 2 \* (1 + 1) - 2 - 3 = 0

• For cell (0, 0), grid[0][0] = 1, increment rows[0] and cols[0]: rows = [1, 0], cols = [1, 0, 0]

• For cell (1, 1), grid[1][1] = 1, increment rows[1] and cols[1]: rows = [2, 1], cols = [1, 1, 1]

3. Now that we have the sums of 1s in each row and column, we can initialize the diff matrix filled with zeros:

2. Loop over each cell in grid. If we find a 1, increase the respective count in rows and cols:

This diff matrix represents the sum of 1s in each row and column, minus the sum of 0s for each respective cell in grid.

def onesMinusZeros(self, grid: List[List[int]]) -> List[List[int]]:

# 1. The first two loops (nested) are executed to calculate the sum of the values in each row and column. These loops go through all

**Time Complexity** 

Time and Space Complexity

the elements of the matrix once. Therefore, for a matrix of size  $m \times n$ , the time complexity of this part is  $0(m \times n)$ . 2. The third set of nested loops is used to calculate the diff matrix. They also iterate over every element in the matrix, leading to a

3. The space taken up by variables m, n, i, j, r, c, and v is constant, 0(1).

The given code consists of three distinct loops that iterate over the elements of the grid:

- time complexity of O(m \* n) for this part as well. Adding both parts together doesn't change the overall time complexity since they are sequential, not nested within each other. Hence, the overall time complexity of the algorithm is 0(m \* n).
- Space Complexity
  - 1. Two additional arrays rows and cols are created, which have lengths m and n, respectively. This gives a space complexity of O(m + n).

Analyzing the space complexity:

Therefore, the total space complexity of the algorithm is 0(m \* n + m + n). Since m \* n dominates for large matrices, the overall

2. A new matrix diff of size m x n is allocated to store the results. This contributes 0(m \* n) to the space complexity.

space complexity can be simplified to 0(m \* n).
