2393. Count Strictly Increasing Subarrays

Dynamic Programming

Problem Description

<u>Array</u>

Math

You are given an array nums with positive integers. The task is to find out how many subarrays within this array are in strictly increasing order. A subarray is defined as a consecutive sequence of elements from the given array.

Intuition

Medium

strictly increasing subarrays. An incrementing counter is maintained to track the length of each found increasing subarray. As the outer loop moves through the array, the inner loop expands the current subarray window as long as the next element is

The intuition behind the solution is to use a two-pointer approach to iterate through the array and identify all the consecutive,

greater than the previous one, indicating an increasing sequence. When the inner loop finds that the sequence is no longer increasing, it stops, and the number of subarrays that can be formed with the identified sequence is calculated. To calculate the number of strictly increasing subarrays that fit within the length of the contiguous sequence, we use the formula

for the sum of the first n natural numbers, which is n(n + 1) / 2. This formula is applied because every element in the increasing subarray can be the start of a new subarray, and the number of subarrays ending at each element increases by one for each additional element. Once counted, the outer loop moves to the end of the previously identified increasing subarray to begin the search for the next

sequence. This process continues until the end of the array is reached. The solution has linear time complexity since each element is visited only once by the inner loop.

The given solution uses a simple algorithm with the help of two pointers, i and j. The Python code uses a while loop to iterate

Solution Approach

over the array with its index i. Inside this loop, another while loop is initiated with index j set to i + 1. Here's a breakdown of the approach: 1. Initialize an answer variable ans to zero. This will keep the count of strictly increasing subarrays. 2. Start the outer loop with i at zero, and it will run until it reaches the length of nums.

- 3. Inside the outer loop, immediately start the inner loop with j = i + 1.
- 4. Continue the inner loop as long as j is less than the length of nums and the current element nums[j] is greater than the previous element

6. Calculate the count cnt of consecutive increasing numbers as j - i.

- nums [j 1] (the condition for a strictly increasing subarray). 5. If the condition satisfies inside the inner loop, increment j to expand the current window of the increasing subarray.
- 7. Use the formula (1 + cnt) * cnt // 2 to add the number of subarrays that can be formed within the window i to j 1 to ans. This formula
- derives from the sum of the first n natural numbers formula n * (n + 1) / 2, as each element of the subarray can be the starting element for
- a new subarray, adding to the total count. 8. Assign i to j to move to the end of the current strictly increasing sequence and then look for the next one in the outer loop. 9. After the outer loop concludes, return the cumulative count ans as the result.
- This approach does not require any additional data structures and relies on a simple calculation and pointer manipulation to arrive at the solution.
- **Example Walkthrough**

1. Initialize ans to 0. This is our counter for strictly increasing subarrays.

```
3. Start the inner loop by setting j = i + 1, which is 1 (the second element, which has a value of 2).
```

Let's walk through the solution approach with a small example array nums = [1, 2, 3, 1, 2].

Initialize the answer and the starting index

Move to the next index to compare with the current element

// Initialize end index of the current subarray to be just after startIdx

// Use the formula for the sum of first n numbers to calculate combinations

totalSubarrays += (currentSubarrayCount + 1) * currentSubarrayCount / 2;

while (endIdx < arraySize && nums[endIdx] > nums[endIdx - 1]) {

long currentSubarrayCount = endIdx - startIdx;

return count; // Return the total count of the subarrays

// Index 'i' is used to iterate through the array with initialized value of 0

// Inner loop to find increasing consecutive subarray starting at 'i'

++j; // Increase 'j' if the current element is greater than the previous

// Initialize 'j' for the inner loop as the next index of 'i'

function countSubarrays(nums: number[]): number {

// 'n' stands for the length of the input array 'nums'

// Loop over the elements of the array using 'i'

// Initialize the count of subarrays

// Extend the end index until it no longer forms a strictly increasing subarray

// Calculate the count of increasing subarrays that can be formed between startIdx and endIdx

subarray_count = start_index = 0

while start index < len(nums):</pre>

10. Move i to j, so i = 3. The value at nums [i] is 1.

5. Continue incrementing j. It becomes 2, and nums[j] is 3 which still satisfies nums[j] > nums[j - 1].

2. Begin with i = 0. The value at nums[i] is 1.

6. Incrementing j again to 3, we get nums[j] = 1. This is not greater than 3 (the previous value), so the inner loop stops here. 7. Calculate the count cnt as j - i, which gives 3 - 0 = 3. We've found a strictly increasing subarray of length 3.

4. Now, nums[j] > nums[j - 1] because 2 (at j) is greater than 1 (at i). Hence, there is a strictly increasing subarray from index 0 to index 1.

8. We can form (1 + cnt) * cnt // 2, which is (1 + 3) * 3 // 2 = 6 strictly increasing subarrays from index 0 to index 2. 9. Add 6 to ans. Now, ans is 6.

13. Calculate the count cnt as 1 because only one pair 1, 2 satisfies the condition of a strictly increasing subarray.

- 11. Repeat the process with the new value of i. Start the inner loop with j = i + 1, which is 4. We have nums [j] = 2. 12. Continue as nums[j] > nums[j - 1] (2 > 1), but since j is now pointing to the last element, the inner loop will stop after this.
- 14. We can form (1 + cnt) * cnt // 2, which is (1 + 1) * 1 // 2 = 1 additional strictly increasing subarray from index 3 to index 4. 15. Add 1 to ans. Now, ans is 6 + 1 = 7.
- 16. There's no more elements beyond j = 4 to check, so we finish iteration.
- At the end of this process, we have determined that there are 7 strictly increasing subarrays within nums.
- class Solution: def countSubarrays(self, nums: List[int]) -> int:

Loop over the array to find all increasing subarrays

int startIdx = 0;

// Total number of elements in the array

int arraySize = nums.length;

while (startIdx < arraySize) {</pre>

int endIdx = startIdx + 1;

// Iterate over the array

endIdx++;

Solution Implementation

Python

```
end_index = start_index + 1
            # Check if the next element is greater than the current
            # Continue moving end index as long as we have an increasing subarray
            while end index < len(nums) and nums[end_index] > nums[end_index - 1]:
                end_index += 1
            # Calculate the length of the current increasing subarray
            length = end_index - start_index
            # Compute the number of possible contiguous subarrays in the increasing subarray
            # and add to the total count
            subarray count += (1 + length) * length // 2
            # Move start index to the next point to start checking for a new subarray
            start index = end index
        # Return the total count of increasing subarrays
        return subarray_count
Java
class Solution {
    // Method to count strictly increasing contiguous subarrays within an array.
    public long countSubarrays(int[] nums) {
        // Initialize count of subarrays as 0
        long totalSubarrays = 0;
        // Start index of the current subarray
```

```
// Move the start index to the end index for the next iteration
            startIdx = endIdx;
        // Return the total count of strictly increasing subarrays
        return totalSubarrays;
C++
class Solution {
public:
    long long countSubarrays(vector<int>& nums) {
        long long count = 0; // This will hold the total count of valid subarrays
        int start = 0, n = nums.size(); // `start` is the index to mark the beginning of a new subarray
        // Iterate over the array
        while (start < n) {</pre>
            int end = start + 1; // `end` is the index for the end of a growing subarray
            // Extend the subarray until the current element is not greater than the previous one
            while (end < n && nums[end] > nums[end - 1]) {
                ++end;
            // Calculate the number of possible subarrays within the current valid range
            int length = end - start; // Length of the current subarray
            // Use the arithmetic series sum formula to count subarrays: n * (n + 1) / 2
            count += 1ll * (1 + length) * length / 2;
            // Move the start for the next potential subarray
            start = end;
```

while (i < n && nums[i] > nums[i - 1]) { // Calculate the length of the current increasing subarray

};

TypeScript

let count = 0;

while (i < n) {

const n = nums.length;

let j = i + 1;

const length = j - i;

let i = 0;

```
count += ((1 + length) * length) / 2;
        // Set 'i' to 'j' to look for the next segment
        i = j;
    // Return the total count of increasing consecutive subarrays
    return count;
class Solution:
    def countSubarravs(self. nums: List[int]) -> int:
       # Initialize the answer and the starting index
        subarray_count = start_index = 0
       # Loop over the array to find all increasing subarrays
       while start index < len(nums):</pre>
           # Move to the next index to compare with the current element
            end index = start index + 1
           # Check if the next element is greater than the current
           # Continue moving end index as long as we have an increasing subarray
           while end index < len(nums) and nums[end_index] > nums[end_index - 1]:
                end_index += 1
           # Calculate the length of the current increasing subarray
            length = end_index - start_index
           # Compute the number of possible contiguous subarrays in the increasing subarray
           # and add to the total count
            subarray_count += (1 + length) * length // 2
           # Move start index to the next point to start checking for a new subarray
            start_index = end_index
       # Return the total count of increasing subarrays
        return subarray_count
Time and Space Complexity
```

// Calculate the count of subarrays for this segment using the formula for sum of first 'length' natural numbers

Time Complexity The given code consists of a while loop that iterates over the length of the array nums. Inside this loop, there is another while

the number and size of the monotonically increasing subarrays in nums. In the best-case scenario, when all elements are in decreasing order, the outer loop runs n times (where n is the length of the array), and the inner loop runs only once for each element, thus giving a time complexity of O(n). In the worst-case scenario, when all elements are in increasing order, the first inner loop runs n-1 times, the second n-2 times,

and so on. Therefore, the number of iterations would resemble the sum of the first n-1 integers, which is (n-1)*n/2, resulting in

loop that continues as long as the current element is greater than the previous element. This inner loop increments j, effectively

counting the length of a monotonically increasing subarray starting at index i. The time complexity of this algorithm depends on

a time complexity of $O(n^2)$ for this scenario. However, because each element is visited at most twice (once as the end of a previous subarray and once as the beginning of a

Space Complexity

new subarray), the actual time complexity, in general, is O(n).

The space complexity of the provided code is 0(1). This is because the code uses a constant amount of extra space for variables ans, i, and j, regardless of the input size. There are no additional data structures that grow with the size of the input.
