Sorting

Problem Description

Greedy

Array

The problem is asking for the minimum possible product sum of two equal-length arrays. The product sum is the sum of a[i] * b[i] for all possible i, given 0-indexed arrays a and b. The twist in the problem is that while one of the arrays (nums2) must remain in its original order, the other array (nums1) can be rearranged in any order to minimize the product sum.

To provide an example, let's assume we have a = [1,2,3,4] and b = [5,2,3,1]. If we were not allowed to rearrange a, then the product sum would be 1*5 + 2*2 + 3*3 + 4*1 = 22. However, if we can rearrange a, we would try to pair the largest numbers in b with the smallest numbers in a to get the smallest possible product for each pair, thereby minimizing the total product sum.

Intuition

Medium

vice versa. This is because a large number times a small number adds less to the product sum than a large number times another large number. To implement this, both arrays nums1 and nums2 are sorted. For nums1, we sort it in non-decreasing order. This places the smallest

To find the minimum product sum, we should try to multiply the smallest numbers in nums1 with the largest numbers in nums2, and

elements at the start of the array. We do not need to sort nums2 as its order cannot be changed, but for the purpose of the solution, we sort it in non-decreasing order as well.

We then iterate over the arrays, multiplying the i-th element of nums1 with the (n - i - 1)-th element of nums2 which corresponds to the i-th largest element in nums2 because nums2 is sorted in ascending order. The sum of these products gives the minimum product sum possible by this rearrangement.

This method works because sorting nums1 and pairing its elements with the reverse-sorted elements of nums2 ensures that each product added to the sum is as small as it can possibly be considering the constraints of the problem.

The solution involves a few steps as described below:

minimizing the product sum.

Solution Approach

1. Sort the nums1 array in non-decreasing order, which will place the smallest elements at the beginning.

- 2. Sort the nums2 array in non-decreasing order as well, though its original order does not need to be changed for the problem
- statement. This step is purely for ease of implementation to allow us to iterate from one end of nums1 to the other while moving in the opposite direction in nums2. By completing these sorting steps, we can now pair the smallest elements in nums1 with the largest in nums2, which is the key to

3. Initialize a variable res to store the cumulative product sum. 4. Iterate over the length of either nums1 or nums2 (since they are of equal length) using a for loop. Calculate the product by taking

- the i-th element from the sorted nums1 and the element at index (n i 1) from the sorted nums2 array. This effectively reverses the second array during the multiplication process. 5. Add this product to the variable res to keep a running total. 6. After the loop concludes, res contains the minimum product sum, as per the requirements of the problem statement.
- The algorithm used is sorting, which under the hood, depending on the language and its implementation, can be a quicksort,
- mergesort, or similar 0(n log n) sorting algorithm. The rest of the function simply iterates through the arrays, which is an 0(n)

Here is the code breakdown: • nums1.sort(): Sorts the first list in non-decreasing order.

n: Captures the length of the arrays.

operation.

- res: The variable that will accumulate the total product sum.
- for i in range(n): Iterates through each index of the arrays.

• nums2.sort(): Sorts the second list in non-decreasing order.

• res += nums1[i] * nums2[n - i - 1]: Calculates the product of the smallest element in nums1 with the largest remaining

nums2.sort()

- element in nums2 and adds it to res.
- After going through all elements, we simply return res which now holds the minimum product sum. 1 class Solution: def minProductSum(self, nums1: List[int], nums2: List[int]) -> int:

n, res = len(nums1), 0for i in range(n):

two arrays, with the possibility of rearranging nums1 but keeping the order of nums2 fixed.

```
res += nums1[i] * nums2[n - i - 1]
          return res
This is a classic greedy approach that ensures the products of pairs are as small as possible to achieve the global minimum sum.
Example Walkthrough
```

Let's consider two sample arrays nums1 = [4, 3, 2, 1] and nums2 = [1, 2, 3, 4]. Our goal is to minimize the product sum of these

Following the solution approach: 1. Sort nums1 in non-decreasing order to get [1, 2, 3, 4].

2. Sort nums 2 in non-decreasing order for the purpose of calculation to get [1, 2, 3, 4]. Remember that the order of nums 2 isn't actually changed in the final answer—this step is simply to help visualize the process.

3. Initialize res to 0 which will hold the cumulative product sum. 4. Iterate over the arrays, calculating the product sum using the greedy approach:

For i = 3 (fourth pairing):

- \circ The product of nums1[0] and nums2[4 0 1] (the last element of nums2) is 1 * 4 = 4.
- For i = 0 (first pairing):
- For i = 1 (second pairing): \circ The product of nums1[1] and nums2[4 - 1 - 1] (the second last element of nums2) is 2 * 3 = 6.
- For i = 2 (third pairing):
- \circ The product of nums1[3] and nums2[4 3 1] (the first element of nums2) is 4 * 1 = 4. 5. The cumulative sum of these products is 4 + 6 + 6 + 4 = 20, which is stored in res.

 \circ The product of nums1[2] and nums2[4 - 2 - 1] (the third last element of nums2) is 3 * 2 = 6.

This demonstrates the solution approach effectively: by sorting nums1 and pairing each element with the 'opposite' element from nums2 (i.e., the element as far from it as possible in the sorted version of nums2), we achieve the minimum product sum. The implemented Python code will return 20 as the result for this example.

Initialize length of the list for iteration and result variable to store the sum

6. After completing the iteration, res now contains the minimum product sum which, in this case, is 20.

class Solution: def minProductSum(self, nums1: List[int], nums2: List[int]) -> int: # Sort the first list in non-decreasing order nums1.sort() # Sort the second list in non-decreasing order nums2.sort()

Iterate over the lists for i in range(length): # Multiply the i-th smallest element in nums1 with the i-th largest in nums2 15 # and add it to the result. This maximizes the product sum of the min/max pairs. 16

Python Solution

from typing import List

length, result = len(nums1), 0

result += nums1[i] * nums2[length - i - 1]

// Return the calculated minimum product sum

```
# Return the final product sum
19
20
           return result
21
Java Solution
1 class Solution {
       // Method to calculate the minimum product sum of two arrays
       public int minProductSum(int[] nums1, int[] nums2) {
           // Sort both arrays
           Arrays.sort(nums1);
           Arrays.sort(nums2);
           int n = nums1.length; // Number of elements in the array
           int result = 0;
                                // Variable to store the result of the minimum product sum
9
10
           // Iterate through the arrays to calculate the product sum
11
           // Multiply elements in a way that smallest of one array is paired with largest of the other
12
           for (int i = 0; i < n; i++) {
13
               result += nums1[i] * nums2[n - i - 1]; // Add to result by pairing elements
14
15
```

C++ Solution

return result;

```
1 class Solution {
 2 public:
        int minProductSum(vector<int>& nums1, vector<int>& nums2) {
           // Sort both vectors in non-decreasing order.
            sort(nums1.begin(), nums1.end());
            sort(nums2.begin(), nums2.end());
            int size = nums1.size(); // Store the size of the vectors.
            int result = 0; // Initialize result to accumulate the product sum.
 9
10
11
           // Loop through every element of nums1.
           for (int i = 0; i < size; ++i) {
12
               // Multiply the current element in nums1 by the corresponding element from the end of nums2.
13
               // This ensures the smallest number in nums1 is multiplied with the largest in nums2 and so on.
14
                result += nums1[i] * nums2[size - i - 1];
15
16
17
18
           // Return the final min product sum.
19
           return result;
20
21 };
22
```

function minProductSum(nums1: number[], nums2: number[]): number { // Sort both arrays in non-decreasing order. nums1.sort((a, b) => a - b); nums2.sort($(a, b) \Rightarrow a - b);$

Typescript Solution

```
let size = nums1.length; // Store the length of the arrays.
       let result = 0; // Initialize result to accumulate the product sum.
       // Loop through every element of nums1
       for (let i = 0; i < size; ++i) {
           // Multiply the current element in nums1 by the corresponding element from the end of nums2
           // This ensures the smallest number in nums1 is multiplied with the largest in nums2, and so on
12
           result += nums1[i] * nums2[size - i - 1];
14
15
       // Return the final min product sum
16
       return result;
17
18 }
19
Time and Space Complexity
Time Complexity
```

The primary operations in the code are the sorting of nums1 and nums2, followed by a single pass through the arrays to calculate the product sum.

• Sorting: The sort() function in Python typically uses the Timsort algorithm, which has a time complexity of 0(n log n). As there

are two lists being sorted, this operation is performed twice. Single Pass Calculation: After sorting, the code iterates through the lists once, with a single loop performing n iterations, where n

- is the length of nums1 (and nums2). The operations inside the loop are constant time, so this is O(n). The overall time complexity is the sum of the two operations, but since O(n log n) dominates O(n), the total time complexity of the
- algorithm is $O(n \log n)$. **Space Complexity**
- The space complexity of the code is determined by the additional space required apart from the input:

Therefore, the space complexity is O(n).
