2209. Minimum White Tiles After Covering With Carpets String **Dynamic Programming Prefix Sum** Hard

Problem Description

covered. If we skip, we move on to the next tile.

'1' indicates a white tile. We are given a certain number of black carpets (numCarpets) and the length of each carpet (carpetLen). The goal is to cover as many white tiles as possible with these carpets, minimizing the number of white tiles that remain visible. Carpets can overlap, and we need to calculate the minimum number of white tiles that will be left uncovered after optimally placing the carpets.

In this LeetCode problem, we have a binary string floor representing the colors of tiles on a floor, where '0' indicates a black tile and

Leetcode Link

Intuition

position or save it for later. Given the nature of the problem, we can think of a dynamic programming approach where we keep track of the number of carpets left (j) and which position we are at (i) in the string. As we encounter a white tile (represented by '1'), we have two choices: either place a carpet here or skip this tile. If we decide to place a carpet, all tiles from the current position to the length of the carpet will be

carpets can overlap, we have to make decisions at each step regarding where to place a carpet and whether to use it at the current

To solve this problem, we need to find an optimal way to place the carpets to cover the maximum number of white tiles. Since

The solution uses a depth-first search (DFS) function with memoization (achieved through the @cache decorator) to remember the results of subproblems. The DFS function calculates the minimum number of white tiles revealed for each scenario and returns the minimum of covering the current tile or moving ahead. Thus, this approach uses a top-down dynamic programming strategy to optimize carpet placement and achieve the desired result.

The additional array s is maintained to keep track of the cumulative sum of white tiles up to any given position for quick calculation of white tiles left when we decide to skip placing a carpet. This setup aids in optimizing the process by avoiding the need to recount white tiles in subproblems repeatedly. After computing the answer using the DFS approach, the cache_clear() method is called to clear the cache, ensuring that the cache is not filled with stale values from previous test cases.

The implementation of the solution involves dynamic programming combined with depth-first search (DFS) and memoization. Here are the steps and algorithms used in the implementation:

1. **DFS with Memoization**: The main algorithm employed is a recursive DFS function dfs(i, j) that takes two parameters—i, the

current tile index in the floor, and j, the number of carpets remaining. The recursion explores different scenarios of placing or

decorator).

Solution Approach

2. Base Case Handling: The base cases are when we've considered all the tiles (i.e., i >= n, where n is the length of floor), or when there are no carpets left (j == 0). The former case returns 0 since there are no more tiles to cover, and the latter returns

3. Making Decisions: When at a black tile ('0'), we can simply move to the next tile (dfs(i + 1, j)). When at a white tile ('1'),

the total number of white tiles remaining starting from index i to the end (s[-1] - s[i]).

not placing carpets and recalls optimal substructure results via memoization to prevent redundant calculations (@cache

there's a choice to make: either cover it with a carpet (and evaluate dfs(i + carpetLen, j - 1), where i + carpetLen represents skipping all covered tiles and j - 1 decrements the available carpets) or leave it uncovered (and evaluate 1 + dfs(i + 1, j) where 1 represents the current white tile left uncovered). The recursive DFS function returns the minimum of these two scenarios. 4. Cumulative Sum Array: The array s serves to pre-compute the prefix sum of white tiles at each index, where s[i + 1] = s[i] +

int(floor[i] == '1'). This allows fast calculation of white tiles over a range of indices, optimizing the process when

determining how many white tiles would remain if no carpet is placed starting from a particular index.

= 2, and carpetLen = 2. We aim to cover as many white tiles as possible with these carpets.

Let's say we decide to place a carpet. Now at index 2, we have a choice again:

def minimumWhiteTiles(self, floor: str, num_carpets: int, carpet_len: int) -> int:

Return the sum of white tiles starting from the current index

We have the choice to place a carpet or leave the tile exposed

return min(dfs(index + 1, remaining_carpets), # Leave tile exposed

If the current tile is already black, just move to the next tile

if index >= n or remaining_carpets == 0:

if floor[index] == '1':

min_white_tiles = dfs(0, num_carpets)

private int dfs(int position, int remainingCarpets) {

if (memo[position][remainingCarpets] != -1) {

// Save the result to the memoization table

memo[position][remainingCarpets] = minWhiteTiles;

return memo[position][remainingCarpets];

if (position >= floorLength) {

if (remainingCarpets == 0) {

// Consider two scenarios:

return minWhiteTiles;

int minWhiteTiles = Math.min(

return 0;

// If we have reached past the end of the floor, no more white tiles to cover

// If we have no carpets left, return the number of white tiles until the end

// If the result has been computed before, return it from the memoization table

// 1. Cover the current tile with a carpet and move the position by carpetLength

1 + dfs(position + 1, remainingCarpets), // not using a carpet here

dfs(position + carpetLength, remainingCarpets - 1) // using a carpet

return prefixSums[floorLength] - prefixSums[position];

// If the current floor tile is not white, go to next tile

// 2. Leave the current tile white and move to the next tile

if (prefixSums[position + 1] == prefixSums[position]) {

return dfs(position + 1, remainingCarpets);

return suffix_sum[n] - suffix_sum[index]

return dfs(index + 1, remaining_carpets)

If the current tile is white, we need to consider it

At index 0, we have a white tile. We have two choices:

Place a carpet and move two tiles ahead, dfs(2, 1).

scenario yielding the minimum number of white tiles left uncovered.

Skip the tile, leaving it uncovered, 1 + dfs(1, 2).

2. Recursive DFS Call: We start the DFS process from index 0 with all carpets available (dfs(0, 2)).

floor with all carpets available. Once the result is computed, dfs.cache_clear() is called to reset the memoization before handling the next test case. The intelligent use of depth-first search with memoization to remember previous results, combined with cumulative sum logic for efficiency, brings the complexity of an otherwise exponential brute force solution down to a manageable level, enabling the solving

5. Calling DFS and Clearing Cache: The solution ultimately calls dfs(0, numCarpets) to start the process from the beginning of the

1. Initialization: We first create a cumulative sum array s with an additional 0 at the beginning to handle zero-indexed arrays easily. For the string "1100101", s = [0, 1, 2, 2, 2, 3, 4, 5]. This array will help in quickly calculating the number of white tiles we have between any two given indices.

Let's use a small example to illustrate the solution approach. Suppose the binary string floor is "1100101", we are given numCarpets

configuration.

3. Making Decisions:

of larger inputs effectively.

Example Walkthrough

 Place a carpet from 2 to 4 and move carpet length ahead, dfs(4, 0). ■ Skip the tile, s[-1] - s[2] + dfs(3, 1) (since j is not 0, we perform s[-1] - s[2] to count the remaining white tiles starting from index 2).

After making optimal choices at each step and using memoization to avoid repeated calculations, the recursive function will yield the

minimum number of white tiles that will remain uncovered. For the above example, two carpets will cover tiles from indices 0 to 1 and

2 to 3 or 4 to 5, depending on the decision made at index 2. In both cases, there will be 2 white tiles showing—the minimum for this

4. Evaluating scenarios with memoization: Each of these scenarios is evaluated, and the DFS function will keep track of the

5. Base Cases: Whenever i >= n (beyond last index) or j == 0, we handle the base cases as previously detailed.

- Upon finishing the evaluation, we call dfs.cache_clear() to prepare the memoization for the next test case if needed, without interference from the current state. Following this approach results in an efficient solution to the problem.
 - # Using LRU cache to memorize results reducing time complexity @lru_cache(maxsize=None) def dfs(index, remaining_carpets): # If we've considered all tiles or have no remaining carpets

dfs(index + carpet_len, remaining_carpets - 1)) # Place a carpet

24 # Precompute the prefix sum of white tiles to use later in calculation 25 $suffix_sum = [0] * (n + 1)$ 26 for i in range(n): suffix_sum[i + 1] = suffix_sum[i] + (floor[i] == '1') 27 28

Calculate the minimum number of white tiles using DFS starting from tile index 0 with all carpets available

- 32 # Clear the cache for the lru_cache decorator as it's a good practice to free up memory after use 33 dfs.cache_clear() 34 return min_white_tiles 35 36 # Example usage (uncomment to run): 37 # sol = Solution() # print(sol.minimumWhiteTiles("10101", 2, 2)) # Should output the minimum number of white tiles 39 Java Solution class Solution { private int[][] memo; // memoization table private int[] prefixSums; // prefix sums array for '1's in the floor string private int floorLength; // length of the 'floor' string 4 private int carpetLength; // the length of a single carpet 5 6 public int minimumWhiteTiles(String floor, int numCarpets, int carpetLen) { floorLength = floor.length(); 8 9 memo = new int[floorLength][numCarpets + 1]; 10 // Initialize the memoization table with -1 to indicate uncalculated states 11 for (int[] row : memo) { 12 13 Arrays.fill(row, -1); 14 15 16 // Precompute the prefix sums of '1's in the floor string 17 prefixSums = new int[floorLength + 1]; for (int i = 0; i < floorLength; ++i) {</pre> 18 prefixSums[i + 1] = prefixSums[i] + (floor.charAt(i) == '1' ? 1 : 0); 19 20 21 22 carpetLength = carpetLen; 23 24 // Start the recursive depth-first search from position 0 with all carpets available 25 return dfs(0, numCarpets); 26 27

return prefixSum[n] - prefixSum[pos]; // No carpets left: return count of white tiles.

// This function initializes the dp array and computes the minimum number of white tiles after placing the carpets.

Time Complexity The overall time complexity of the given algorithm is determined by the number of states the dynamic programming needs to

memoization.

carpetLen tiles)

• The function dfs is a recursive function with two parameters i and j, which represent the current index in the string floor and the number of carpets left to use, respectively. i can have a maximum of n different states, where n is the length of the floor string. • j can have a maximum of numCarpets + 1 different states (ranging from 0 to numCarpets).

current position or not. Map this into time complexity, assuming n is the length of the string floor and c is the number of carpets numCarpets:

• For each state, dfs makes at most two recursive calls, representing the two choices available: either place a carpet at the

T(n, c) = T(n - 1, c) (move to the next tile without placing a carpet) + T(n - carpetLen, c - 1) (place a carpet and skip

compute and the time it takes to compute each state. The algorithm uses a top-down dynamic programming (DFS) approach with

- Solving this, we have 0(n * c * c2) time complexity, where c2 is the work done for each state. Hence, the total time complexity is 0(n * c * 2).
- The space complexity of the algorithm includes the space required for memoization and the depth of the recursive call stack.

Space Complexity

• Memoization requires 0(n * c) space since it stores a result for each possible state (i, j). The recursion depth can go as deep as n because we might go down one level deeper for each tile.

Therefore, the overall space complexity is 0(n * c) + 0(n). Since 0(n * c) is the dominating term, the simplified space complexity is also 0(n * c).
